CERTIFICATE

This is to certify that the present work, "Simulation of long tube vertical Evaporator" has been carried out under my supervision and has not been submitted elsewhere for a degree.

Date: 30th July 1974

(Dr.) H. Veeramani
Assistant Professor
Department of Chemical Engineering
Indian Institute of Technology
Kanpur-208016, India.

ACKNOWLEDGEMENT

The author is deeply indebted to Dr. H. Veeramani for his guidance, interest in the work, appropriate decisions and encouraging approach to the problems encountered.

Thanks are due to Mr. R.P. Shukla, Mr. D. Kumar, Mr. S.C. Shenoy Mr. B.P. Pandey, Mr. R.K. Srivastava and other friends for encouragement and fruitful discussions.

Lastly the author wishes to acknowledge Mr. T.R. Gupta and Mr. R.B. Singh for efficient typing and Mr. D.S. Panesar for preparing the drawings.

ABSTRACT

✓ [A simulation programme is developed to predict the profiles of liquor temperature, concentration, heat flux, overall heat transfer co-efficient, pressure, pressure gradient, void fraction and vapor quality along the tube length of a natural circulation LTV evaporator. These quantities are predicted for the nonboiling and boiling sections of an evaporator tube from a combination of the following expressions: continuity, momentum and energy balance equations, and frictional pressure drop and holdup correlations for single phase and two phase flow, heat transfer correlation for the nonboiling, nucleate boiling and annular film regions, and correlations for the engineering properties of the process liquor such as thermal conductivity, viscosity, density, surface tension, boiling point rise and specific heat. A stepwise computation procedure has been developed starting with feed inlet conditions assuming a series of differential sections in the nonboiling and boiling sections of the tube and using the criteria of a maximum in liquor temperature profile and a minima in the pressure gradient curve for the transition from nonboiling to nucleate boiling and from nucleate boiling to annular film region respectively.

Results from this simulation programme agree with Badger's experimental data with an overall accuracy of 15% and agreement is within 3% for the temperature profile and an average deviation of 25% for the overall heat transfer co-efficient based on Gudmundson's experimental data for water. The model is applied to bamboo, baggase and pine black liquors, ✓ over the concentration range 12-28% and the pronounced effect of viscosity

on heat transfer rates is illustrated for the following conditions:

Feed-rate 100 tons/hr, temperature 50°C and concentration 12.0%;

Evaporator-tube diameter 51 mm, length 7.6 m and number of tubes 300,

dirt scale resistance $R_D = 0.45 \text{ m}^2 \text{ }^\circ\text{K/KW}$. The nonboiling section length is 0.92 m and 2.13 m for bamboo and bagasse black liquors; the corresponding values of the overall heat transfer coefficient are $2.4\text{--}2.7 \text{ KW/m}^2 \text{ }^\circ\text{K}$ (from 50°C, 0.9 cp to 106°C, 0.45 cp) and $0.8\text{--}1.1 \text{ KW/m}^2 \text{ }^\circ\text{K}$ (from 50°C, 4.7 cp to 102.4°C, 1.9 cp) with clean surfaces. In the boiling section the overall heat transfer co-efficient values are $2.4\text{--}3.1 \text{ KW/m}^2 \text{ }^\circ\text{K}$ and $2.5\text{--}3.3 \text{ KW/m}^2 \text{ }^\circ\text{K}$ for bamboo and bagasse black liquors respectively; the final concentration, temperature and viscosity values are 27.8%, 95.3°C, 1.1 cp for bamboo and 25.9%, 86.2°C, 9.8 cp for bagasse black liquors assuming clean tube surface. With the inclusion of the dirt scale resistance the nonboiling length increases to 1.83 m and 2.75 m with a corresponding decrease in heat transfer co-efficient to $1.2\text{--}1.3 \text{ KW/m}^2 \text{ }^\circ\text{K}$ and $0.6\text{--}0.7 \text{ KW/m}^2 \text{ }^\circ\text{K}$ for bamboo and bagasse black liquors respectively in the nonboiling section. In the boiling region the dirt resistance decreases heat transfer co-efficient to $1.2\text{--}1.4 \text{ KW/m}^2 \text{ }^\circ\text{K}$ and $1.2\text{--}1.45 \text{ KW/m}^2 \text{ }^\circ\text{K}$ for bamboo and bagasse black liquors respectively giving a final liquor with concentration, temperature, viscosity of 15.7%, 103°C, 0.41 cp for bamboo and 15.4%, 99°C, 2.0 cp for bagasse black liquor.

CHAPTER 1

INTRODUCTION

Natural circulation long tube vertical (LTV) evaporators are widely used for the concentration of solutions such as milk, fruit juice, spent pulping liquors etc. This study deals with the development of a model to predict changes in evaporation capacity and to recommend auxiliary heat exchange equipment that may be needed to accommodate a large change in the viscosity of the process liquor. A good example is the evaporation of weak black liquors from alkaline pulping process. Paper mills in India use bamboo as the major raw material and smaller amounts of mixed hardwoods, salai, baggase, grasses, pine etc. Increasing quantities of baggase and eucalyptus may also become available to the paper industry. The evaporation plant in a paper mill must be capable of handling bamboo, baggase, eucalyptus black liquors and also mixed black liquors whose viscosities vary considerably over the same range of concentration and temperature (38).

Fluid flow and heat transfer mechanisms in a LTV evaporator result in nonboiling, nucleate boiling and annular film regions along the tube length and determine the changes in solution temperature and concentration. In simulating the performance of a LTV evaporator process feed liquor conditions such as flow rate, temperature, concentration and pressure are usually available. Simulation consists in predicting the profiles of liquor temperature, concentration, heat flux and overall heat transfer co-efficient along the length of the evaporation tube. These computations would also give variation in pressure, pressure gradient, void fraction and vapor quality along the tube length. All these

quantities can be predicted for the given evaporator unit from a combination of the following expressions: Continuity, momentum and energy balance equations, and frictional pressure drop and holdup correlations for single phase and two phase flow, heat transfer correlation for the nonboiling, nucleate boiling and annular film regions, and correlations for the engineering properties of the process liquor such as thermal conductivity, viscosity, density, surface tension boiling point T_{ise} and specific heat. Computations would begin with the feed inlet conditions at the bottom of the evaporation tube and proceed through the nonboiling, nucleate boiling and annular film regions, and thus traverse the entire tube length. Computations are carried out in a stepwise manner assuming a series of differential sections of the evaporator tube and using the criteria of a maximum in liquor temperature profile and a minima in the pressure gradient curve for the transition from nonboiling to nucleate boiling and from nucleate boiling to annular film region respectively.

Simulation programme developed in this study is compared with the experimental results of Brooks and Badger⁽⁴⁾ and Gudmundson^(2,45) for evaporating water and subsequently used for the concentration of pine, bamboo and bagasse black liquors.

CHAPTER 2

Fluid Flow Pattern & Heat Transfer Mechanisms in a Long Tube Vertical Evaporator

LTV evaporators generally consist of 2.5 - 7.5 cm. diameter, 5-10 meter long tubes. Fluid flow patterns and heat transfer mechanisms obtainable for a liquor feed below its saturation temperature are shown in Fig.2.1. The following flow patterns and corresponding heat transfer mechanisms are normally observed:

1. Single Phase Liquid Flow (Convective Heat Transfer): Solution is heated to its saturation temperature by convection in the nonboiling section with the cold feed introduced at the bottom of the tube.
2. Bubble Flow (Nucleate Boiling): Superheating of the liquor adjacent to the tube wall occurs to some extent and small bubbles of vapor form on the heat transfer surface and results in a bubble flow pattern as they are released from the surface.
3. Slug Flow (Nucleate Boiling and Convective Heat Transfer): With an increase in number and size, the bubbles coalesce and two phase slug flow commences up the tube. In the beginning heat transfer takes place by nucleate boiling mechanism but with the increase in slug size, heat transfer takes place through liquor film by forced convection mechanism.
4. Annular Film Flow (Forced Convection): The increase in vapor velocity results in a central core of vapor flow and an annular climbing film of liquor and heat is transferred across this liquor film by forced convection.
5. Mist Flow (Forced Convection): With an increase in temperature gradient, dry patches begin to appear on the tube surface and liquid droplets are

Fig.2.1- Fluid flow pattern and heat transfer in a LTV evaporator.

carried as a mist by the high velocity vapor. Heat transfer takes place through liquor film and at places of dry patches, directly to vapor by forced convection.

6. Single Phase Vapor Flow (Forced Convection): As the vapor rate is increased liquor entrainment becomes more and more predominant until, finally, the liquid annulus disappears and all the liquid is carried in the vapor core, giving essentially vapor flow up the tube.

In a commercial LTV evaporator, a certain length of the tube is used in heating the feed to the saturation temperature; in normal operation bubble flow, slug flow and annular film flow regions are encountered. Mist and single phase vapor flow patterns are not usual in chemical process evaporators unless very large temperature gradients are impressed on the system; further evaporation in a single pass is limited to less than 50-60%. Thus it is necessary to consider regions (1) to (4) listed above in a detailed analysis of heat transfer in a LTV evaporator.

The flow regions and the accompanying heat transfer mechanisms, shown in Figure 2.1 are not very distinct and there is considerable overlap in actual operation. For the purpose of this analysis the following heat transfer mechanisms are considered: 1) Convection (nonboiling section) 2) Nucleate boiling (bubble flow and part of slug flow region) 3) Forced convection (remainder of slug flow and annular film region).

Differences in fluid flow pattern and heat transfer mechanisms would result in a variation of the heat transfer co-efficient along the length of the evaporator tube. There is a slight maxima in liquor

temperature caused by pressure drop indicating the start of nucleate boiling region after the nonboiling section. Likewise transition from slug flow to the annular film flow regime is accompanied by a minima in the pressure gradient curve along the tube caused by the high void fraction of vapor (0.8-0.9) which in turn leads to high frictional pressure drop. This has been observed by Anderson et.al.⁽¹⁵⁾ in their experimental findings. These criteria may be used to predict approximately the sections of the tube lengths where single phase liquid flow, bubble & slug flow, and annular film flow regions occur during evaporation. Heat transfer co-efficients in these sections can be predicted using the appropriate available correlations. These are discussed in Chapter 4.

As the liquor traverses up the tube, liquor temperature increases due to sensible heat transfer and pressure decreases as a result of static and frictional forces in the nonboiling section; in this section liquor concentration remains constant as there is no evaporation. Changes in liquor temperature, pressure, pressure gradient and heat flux in a differential length of the nonboiling zone can be predicted by continuity, momentum & energy balance equations; and frictional pressure drop equation for the single phase liquid and heat transfer correlation. The transition to nucleate boiling occurs when the liquor temperature is equal to the saturation temperature corresponding to the pressure at that point in the tube. In the nucleate boiling region two phase flow starts with an increase in the volume of the vapor by evaporation accompanied by an increase in the liquor concentration. A differential length in this region can be considered for predicting the changes in liquor temperature and concentration, pressure,

pressure gradient, quality, void fraction and heat flux by applying continuity, momentum & energy balance equations alongwith void fraction, two phase frictional pressure drop and heat transfer correlations.

The stepwise procedure can be repeated until a minima appears in the pressure gradient along the length indicating the start of the annular film flow region. Changes occuring in this section can likewise be predicted by applying continuity, momentum & energy balance equations along with other equations to differential segments of this region in a stepwise manner until the evaporator tube length has been traversed. These stepwise calculation procedures are discussed in Chapter 5.

CHAPTER 3

ENERGY, MOMENTUM & CONTINUITY BALANCES FOR NONBOILING AND BOILING REGIONS

Energy, Momentum & Continuity balance equations are necessary for the simulation of the LTV evaporator. These equations will differ for the nonboiling section (single phase) and boiling section (two phase flow) of the evaporator tube length.

The appropriate balances applicable to the single phase region are discussed first. In the two phase flow regime energy, momentum & continuity balance expressions are obtained for (1) homogeneous model and (2) slip model. The former model assumes that liquor and vapor travel at same velocity where as the latter model is developed on the basis of different velocities for liquor and vapor phases.

A. SINGLE PHASE LIQUID

The following assumptions are made for the one-dimensional analysis of the single-phase flow existing in the nonboiling section of a

e

evaporator tube:

1. There is no radial variation of pressure, temperature, velocity & density.
2. Change in the Kinetic Energy is negligible.

Energy Balance:

Consider a differential section of the nonboiling section (dZ) shown above. Equation (3.1) gives the general differential form of the energy equation.

$$d(\text{Enthalpy}) + d(\text{Kinetic Energy}) + d(\text{Potential Energy}) = dq - dW \quad (3.1)$$

The terms in equation 3.1 can be evaluated separately as described below.

dH = Enthalpy of mixture leaving differential section

- Enthalpy of mixture entering differential section

$$= C_L dT, \text{ Btu/lb-m} \quad (3.2)$$

$$\text{Differential change in Kinetic Energy} = 0 \quad (3.3)$$

$$\text{Differential change in Potential Energy} = \frac{dZ}{J g_c} \quad (3.4)$$

The amount of heat transferred per pound mass of fluid flowing is given by equation 3.5.

$$dq = \frac{Q \cdot 2\pi r \cdot dZ}{W_L \cdot 3600} - \frac{Q \cdot 2\pi r \cdot dZ}{\int_L^P u \cdot C_1 \cdot 3600} \quad (3.5)$$

The amount of work done by the system on the surroundings

$$dW_s = 0 \quad (3.6)$$

Substituting equations 3.2 to 3.6 in equation 3.1, energy equation

gives:

$$dT = \frac{1}{C_L} \left[\frac{Q_c 2 \pi r \cdot dz}{C_1 u \rho_L 3600} - \frac{dz}{J} \frac{g}{g_c} \right] \quad (3.7)$$

Equation 3.7 can be used to predict the temperature change in a differential section of the nonboiling zone.

Momentum Balance:

Application of Newton's second law of motion to the fluid in the differential section (dz) gives the momentum balance equation 3.8.

$$\begin{aligned} \text{Forces of acceleration} - \text{forces of deceleration} \\ = \text{change in momentum of fluid} \end{aligned} \quad (3.8)$$

Change in the momentum of fluid is

$$\frac{\rho_L u C_1 (u + du)}{g_c} - \frac{\rho_L u C_1 u}{g_c} = 0 \quad (3.9)$$

When the equation 3.9 is stated mathematically, it becomes

$$C_1 P - (P + dP) C_1 - \frac{g}{g_c} \rho_L C_1 dz - \tau_w \pi D dz = 0 \quad (3.10)$$

Frictional pressure drop and shear stress at wall can be related

$$\text{as} \quad \tau_w = \frac{dP_F}{dz} \frac{C_1}{P} = \frac{dP_F}{dz} \frac{D}{4} \quad (3.11)$$

By using equation 3.11, equation 3.10 can be rewritten as:

$$dP = \frac{-g \rho_L dz}{g_c} - \left(\frac{dP_F}{dz} \right) dz \quad (3.12)$$

Equation 3.12 can predict the change in pressure along the tube length for the nonboiling section.

B. TWO PHASE FLOW (HOMOGENEOUS MODEL)

For making a one-dimensional analysis of the two-phase flow in the boiling section of an evaporator tube, the following assumptions are made:

1. No radial variation of pressure, temperature, velocity, quality and specific heat (This implies homogeneous vapor liquid mixture).
2. Relative velocity between the vapor and liquid is equal to zero. (no slip occurs between the vapor and liquid).
3. Vapor and liquid are in equilibrium.
4. Density of vapor-liquid mixture is given as

$$\rho = (1 - \alpha) \rho_L + \alpha \rho_V$$

Energy Balance:

Consider a differential section of the nonboiling section (dz) shown above. The general energy equation 3.1 is applied to this differential

section by evaluating each term separately.

$$\begin{aligned} dH &= \text{Enthalpy of mixture leaving differential section} \\ &- \text{Enthalpy of mixture entering differential section} \end{aligned} \quad (3.13)$$

The mixture leaving the section with a temperature $(T + dT)$ and a quality $(X + dX)$ had an enthalpy of

$$\begin{aligned} &(1-X-dX) C_L (T-T_o+dT) + (X+dX) \lambda + (X+dX) C_p (T+dT-T_o) \\ &= (1-X) C_L (T-T_o) + (1-X) C_L dT - (T-T_o) C_L dX + X \lambda \\ &\quad + \lambda dX + X C_p (T-T_o) + (T-T_o) C_p dX \end{aligned} \quad (3.14)$$

The mixture entering the section with a temperature T and a quality X had an enthalpy of

$$(1-X) C_L (T-T_o) + X \lambda + X C_p (T-T_o) \quad (3.15)$$

dH can be obtained from equations 3.14 and 3.15, and ignoring second order differentials gives equation 3.16.

$$dH = (1-X) C_L + \lambda dX + X C_p dT \quad (\text{if } T_o = T) \quad (3.16)$$

The differential change in Kinetic energy ($dK.E.$) is

$$\begin{aligned} d(K.E.) &= \frac{(u+du)^2}{2 g_c J} - \frac{u^2}{2 g_c J} \\ &= \frac{u du}{g_c J} \end{aligned} \quad (3.17)$$

The differential change in potential energy ($dP.E.$) is

$$d(P.E.) = \frac{dz g}{J g_c} \quad (3.18)$$

The amount of heat transferred per pound mass of fluid flowing (dq) is

$$dq = \frac{Q \cdot 2 \pi r \cdot dz}{3600 \cdot W_L} = \frac{Q \cdot 2 \pi r \cdot dz}{\rho u C_1 \cdot 3600} \quad (3.19)$$

The amount of work (dW_s) done by the system on the surrounding is

$$dW_s = 0 \quad (3.20)$$

Combining equations 3.16 to 3.20 and equation 3.1 gives the energy equation for two-phase flow.

$$(1-X) C_L dT + \lambda dX + X C_P dT + \frac{u du}{g_c} + \frac{dz}{J} \frac{g}{g_c} = \frac{Q \cdot 2 \pi r \cdot dz}{\int u C_1 \cdot 3600} \quad (3.21)$$

Equation 3.21 can be used to predict temperature change or heat flux in the differential section.

Momentum Balance:

Momentum balance expression represented by equation 3.8 can be applied to the differential section to give equation 3.22.

$$\begin{aligned} C_1 P - (P + dP) C_1 - \int C_1 \frac{dz}{g_c} \frac{g}{g_c} - \tau_w \pi D dz \\ = \frac{\int u C_1 (u + du)}{g_c} - \frac{\int u C_1 u}{g_c} \end{aligned} \quad (3.22)$$

By using equation 3.11, equation 3.22 can be rewritten for pressure drop in the differential section

$$-dP = \frac{\int dz}{g_c} \frac{g}{g_c} + \left(\frac{dP_F}{dz} \right) dz + \frac{\int u du}{g_c} \quad (3.23)$$

Equation 3.23 can be used to predict pressure drop in the differential section.

Continuity Balance:

Continuity equation for the boiling section is represented by equation 3.24.

$$W_T = \int u C_1 \quad (3.24)$$

This can be given in differential form for steady flow conditions in the boiling section by equation 3.25

$$u \, dP + \int du = 0 \quad (3.25)$$

Liquor Solid Concentration:

Solids balance for the differential section is given by equation 3.26

$$\text{Total solid entering} = \text{Total solid leaving} \quad (3.26)$$

$$S W_L = S W_L + S dw_L + W_L ds + dw_L ds \quad (3.27)$$

Change in liquor concentration over the differential length of the evaporator is given by equation 3.28.

$$ds = \frac{-S \, dw_L}{W_L + dw_L} \quad (3.28)$$

Mass balance for the evaporation gives

$$dw_L + dw_G = 0 \quad (3.29)$$

Vapor quality of the mixture leaving the section is

$$X + dX = \frac{W_G + dw_G}{W_L + W_G} = X + \frac{dw_G}{W_L + W_G} \quad (3.30)$$

Equation 3.29 and 3.30 can be combined to give

$$dW_L = - (W_L + W_G) dX \quad (3.31)$$

By using equation 3.31 and 3.28, equation 3.32 can be obtained to predict the change in liquor concentration over a differential segment of the boiling section of the tube.

$$dS = \frac{S(W_L + W_G) dX}{W_L - (W_L + W_G) dX} \quad (3.32)$$

C. TWO PHASE FLOW (SLIP MODEL)

This model differs from the homogeneous model in that there is slip between liquid and vapor which is taken into account by the slip model. The following assumptions are made in the analysis.

1. No radial variation of pressure & temperature.
2. Vapor and liquid are in equilibrium.
3. Density of vapor-liquid mixture is given by

$$\rho = (1 - x) \rho_L + x \rho_v$$

Continuity Balance:

Equation 3.33 can be written for continuity balance

$$W_T = W_L + W_G \quad (3.33)$$

If the areas of cross section of the two streams are A_L and A_G .

$$W_L = \rho_L v_L A_L \quad (3.34)$$

$$W_G = \rho_G v_G A_G \quad (3.35)$$

The mass flux of each stream is then

$$G_L = \rho_L v_L (1 - \alpha) \quad (3.36)$$

$$G_G = \rho_G v_G \alpha \quad (3.37)$$

By using the definition of vapor quality (X), the above two equations can be used to give alternative expressions for the overall mass flux.

$$G = \rho_L v_L \frac{(1 - \alpha)}{(1 - X)} = \frac{\rho_G v_G \alpha}{X} \quad (3.38)$$

Momentum Balance:

Many alternative forms of the momentum equation can be derived by manipulating relationships among void fraction, vapor quality, total mass flux, liquor velocity, vapor velocity and other variables. For steady flow in a pipe Wallis⁽⁵³⁾ has given the following expression.

$$\frac{dP}{dZ} = - \frac{dP_F}{dZ} - \frac{G}{g_c} \frac{d}{dZ} \left[X v_L + (1 - X) v_G \right] + \left[\alpha \rho_G + (1 - \alpha) \rho_L \right] \quad (3.39)$$

Combining equation 3.39 with equation 3.38, momentum equation for the differential section can be written

$$\begin{aligned} \frac{dP}{dZ} = - \frac{dP_F}{dZ} = - \frac{G^2}{g_c} \frac{d}{dZ} \left[\frac{(1 - X)^2}{(1 - \alpha) \rho_L} + \frac{X^2}{\rho_G \alpha} \right] \\ - \left[(1 - \alpha) \rho_L + \alpha \rho_G \right] \end{aligned} \quad (3.40)$$

Equation 3.40 can be used to estimate pressure drop along the tube.

Energy Balance:

In energy balance, all terms will be alike as in the homogeneous model equation 3.21 except kinetic energy term

$$d(K.E) = \frac{1}{g_c J} d \left[\frac{X v_G^2}{2} + \frac{(1-X) v_L^2}{2} \right] \quad (3.41)$$

Combining equation 3.38 and 3.41, Kinetic energy term becomes.

$$\begin{aligned} d(K.E) &= \frac{1}{g_c J} d \left[\frac{G^2 X^3}{2 \rho_G^2} + \frac{(1-X)^3 G^2}{2 \rho_L^2 (1-X)^2} \right] \\ &= \frac{G^2}{2 g_c J} d \left[\frac{X^3}{\rho_G^2} + \frac{(1-X)^3}{\rho_L^2 (1-X)^2} \right] \end{aligned} \quad (3.42)$$

Substituting all terms in equation 3.1, energy equation becomes

$$\begin{aligned} (1-X) C_L dT + X C_p dT + \frac{G^2}{2 g_c J} d \left[\frac{X^3}{\rho_G^2} + \frac{(1-X)^3}{\rho_L^2 (1-X)^2} \right] \\ + \frac{dZ}{J} \frac{g}{g_c} = \frac{Q \cdot 2 \pi r \cdot dZ}{\rho u C_1 \cdot 3600} \end{aligned} \quad (3.43)$$

Equation 3.43 can be used for predicting temperature change in the differential section during two phase flow assuming slip model. The change in the liquor concentration for this model will be the same as for the homogeneous model and is given by equation 3.32.

Equation 3.1 to 3.12 are used for the nonboiling section and for the boiling section either equations 3.13 to 3.32 assuming homogeneous model for two phase flow or equations 3.32 to 3.43 based on slip model for two phase flow can be used.

REVIEW OF HEAT TRANSFER, PRESSURE DROP AND HOLD-UP CORRELATIONS
AND LIQUOR PROPERTIES

Fluid flow patterns and heat transfer mechanisms in a LTV evaporator were discussed earlier in Chapter 2. Changes occur in liquor conditions such as temperature, pressure, pressure gradient, concentration and factors relating to two-phase flow behavior such as quality and void fraction, and associated heat flux and overall heat transfer co-efficient along the length of the evaporator tube. All these quantities are determined in simulating the LTV evaporator. These can be predicted for a given evaporator unit from a combination of the following expressions: continuity, momentum & energy balance equations, and frictional pressure drop and holdup correlations for single phase and two phase flows, heat transfer correlations for the nonboiling, nucleate boiling and annular film regions, and correlations for the engineering properties of the process liquor such as thermal conductivity, viscosity, density, surface tension, boiling point rise and specific heat.

Momentum, energy and continuity relations for one dimensional single phase and two phase flow were discussed in detail in Chapter 3. This chapter deals with the following aspect 1) Critical review of heat transfer correlations for an LTV evaporator and recommended expressions for heat transfer, 2) frictional pressure drop and hold-up correlations to be used in this analysis and 3) Engineering properties for the process liquors.

A. Review of Heat Transfer in a LTV Evaporator:

include convective heat transfer, nucleate boiling and forced convective heat transfer. A summary of the available literature pertaining to these heat transfer mechanisms is given in Table 4.1.

Available heat transfer correlations are summarised separately for each of the three sections - non boiling, nucleate boiling and annular film regions. The complete correlating equations are not given; instead only the major variables that are included in the various investigations of heat transfer in LTV units are given. The tube size, liquor systems, accuracy of predictions and the range of application of these correlations are shown in Table 4.1 for the various expressions proposed by different investigators. It is necessary to choose expressions appropriate for the simulation of this investigation from amongst the various equations in Table 4.1. The use of empirical overall coefficients representing the cumulative effects of heat transfer in the different zones and the steam side characteristics are not suitable for the simulation purposes (Equations in section A, Table 4.1). The liquor flow in the non boiling section of a natural circulation LTV unit is in the laminar flow region for which the non boiling heat transfer correlations proposed by Badger et.al.⁽⁶⁾ and Martinelli & Bolter⁽⁴⁷⁾ can be used. Both of these expressions give essentially the same value of the non boiling heat transfer coefficient even though the latter include the effect of natural convection in their correlation (Appendix B). For computational purposes it is simpler to use Badger et.al.⁽⁶⁾ correlation than Martinelli & Bolter expression; in the latter expression non boiling

Table 4.1 : Summary of Correlations for Heat Transfer in a LTV Evaporator

Tube Size	Liquor System	Heat Transfer Correlation	Remarks
<u>A. Overall Heat Transfer Co-efficient (includes nonboiling and boiling regions)</u>			
<u>1. Uchida & Shinkawa (7)</u>			
L = 2.5 m	Water, H_2O-CH_3OH	$U = f(\lambda, \mu, V, F, Pr)$	Prediction within $\pm 15\%$
D = 11.9, 18.6, 25.5 mm			
<u>2. Gudmundson et.al. (2,45)</u>			
L = 10 m	Black Liquor	$U = f(p_1, p_2, p_3, p_4, p_5, C, \mu)$	A least square approach, within $\pm 15\%$ of original data.
D = 51/46 mm			
<u>B. Nonboiling Heat Transfer Co-efficient</u>			
<u>1. Sieder & Tate (46)</u>			
L = 1.55 m	Three different oils	$h = f(Re, Pr)$	Film heat transfer co-efficient. $Re > 2000$
D = 1.9 cm			
<u>2. Martinelli & Boelter (47)</u>			
L = 11.3 - 73.5 cm	Water, oil	$h = f(K, F_1, G^2, F_2, Gr, Pr, X, d_w)$	Film heat transfer co-efficient
D = 1.06-5.04 cm			Prediction within $\pm 20\%$ laminar range only
<u>3. Badger et.al (6)</u>			
L = 5.62 m	Water, sugar	$U_{NB} = f(C_p, \Delta T, f, \mu)$	Over all heat transfer co-efficient. Within $\pm 20\%$. $Re < 10,000$
D = 3.18 cm			

(Table 4.1 continued)

C. Boiling Heat Transfer Co-efficients (includes nucleate and annular film regions)

1.	<u>Brooks & Badger</u> (4)	Water	$U_B = f(W_f, m, \Delta t_{av}, V)$	Over all co-efficient. Prediction within $\pm 20\%$. Empirical in nature.
2.	<u>Stroebe & Badger</u> (5)	Water, sugar, Duponol solutions	$h_B = f(\psi, C_p, \mu, K, \sigma, t_L)$	Film heat transfer co-efficient. within $\pm 20\%$. Empirical in nature.
3.	<u>Coulson & Mehta</u> (8)	Water	$h_B = f(\Delta t, W_f, \mu)$	Film co-efficient.
4.	<u>Pivret & Isbin</u> (9)	Water, Col ₄ , Isopropyl Alcohol, K ₂ CO ₃ solution	$h = f(d_w, K, U_m, \mu, C_p, \sigma)$	Film heat transfer co-efficient. Empirical equation.
5.	<u>Gupta & Holland</u> (17, 18)	Hard water	$U_B = f(\Delta T, \psi, F, T_b, T_i, C_p)$	Over all heat transfer co-efficient within $\pm 16\%$

(Table 4.1 continued)

D. Nucleate Boiling Heat Transfer Co-efficient1. Mcnelly & Joulson (10)

L = 1.52 m	Water, Isopropyl Alcohol, Ethyl Alcohol, Cyclohexane	$Nu = f(d_w, Pr, Re_L, Re_v, \xi, \mu)$ -low heat flux	Film heat transfer co-efficients.
Various dir. tubes		$Nu = f(Pr, q, d_w, \lambda, \mu_L, P, \tau, f)$ -High heat flux	

2. Guerrieri & Talty (48)

L = 1.97 m	Cyclohexane, methanol,	$h = f(h_c, r_*, \xi)$	Film heat transfer co-efficient.
D = 2.54 cm	Benzene, pentene, heptane		

3. Dengler & Addome (11)

L = 6.07 m	Water	$h = f(h_L, F, X_{tt})$	Film heat transfer co-efficient
D = 2.54 cm.			for forced circulation vaporization.

E. Annular Film Heat Transfer Co-efficient1. Guerrieri & Talty (48)

L = 1.97 m	Cyclohexane, methanol,	$h_c = f(h_L, X_{tt})$	Film heat transfer co-efficient
D = 2.54 cm	benzene, pentene, heptane		

(Table 4.1 continued)

2. <u>Denglar & Addoms</u> ⁽¹¹⁾	Water	$h = f(h_L, X_{tt})$	Film heat transfer co-efficient for forced circulation vaporization.
L = 6.07 m			
D = 2.54 cm			
3. <u>Anderson et.al.</u> ⁽¹⁴⁾	Water	Set of equations	Film heat transfer-coefficient. Prediction within <u>±20%</u> . theoretical analysis.
L = 6.07 m			
D = 2.54 cm			
4. <u>Fennan & Tait</u> ⁽¹⁶⁾	Water, CH_3OH , $\text{C}_2\text{H}_5\text{OH}$, Chloroform, 2-propanol, Glycerol	$h = f(C_p, d_w, \rho_L, \sigma, \mu_V, \rho_V)$	Film heat transfer coefficient.
L = 1.91 m			
D = .95-2.54 cm			
5. <u>Kunze</u> ⁽¹⁹⁾	Theoretical analysis	Set of equations	Film heat transfer coe-efficient. $10^{-3} < Pr < 10^4$

Nomenclature for this table are given below:

λ = liquid thermal conductivity

V = vaporization rate

F = feed rate

Γ = Mass rate of liquid per unit length of

$p1-p5$ = adjusted co-efficients

periphery of the evaporator tube length.

C = Correction factor	X = nonboiling length
$F1 \& F2$ = Factors	ΔT = temperature difference
W_f = feed rate	m = factor
v = specific volume of vapor	Δt_L = liquid film temperature difference
U_m = log mean liquid vapor velocity	T_i = inlet temperature
T_b = boiling temperature	ψ = graphically read function of T
q = heat flux	P = pressure
h_c = annular film heat transfer coefficient	h_f = nucleate boiling heat transfer coefficient
h_L = single phase liquid heat transfer coefficient	r_* = radius of minimum size thermodynamically stable bubble
δ = laminar film thickness	X_{tt} = lockhart martinelli parameter
v_v = vapor velocity	
Gr = grashof No.	
Pe = peclet No.	
Gz = graetz No.	

section length is an implicit variable which will require a trial & error procedure for solution.

The heat transfer correlations given (Section C, Table 4.1) represent the boiling heat transfer co-efficient for the combined nucleate boiling and annular film regions and hence cannot be used to predict separately the nucleate boiling & annular film region heat transfer rates.

However, correlations have been proposed for the nucleate boiling region by several investigators (section D, Table 4.1). Guerrieri & Talty⁽⁴⁸⁾ correlation requires laminar film thickness which is often difficult to determine from operating units. Correlations proposed by Dengler & Addams⁽¹¹⁾ applies to forced circulation vaporization only. Monelly & Coulson⁽¹⁰⁾ expressions cover a wide range of equipment geometry & liquor systems and includes the effect of all major parameters. These authors have given two correlations for the nucleate boiling region applicable to low heat flux and high heat flux conditions, and can be used^{to} predict heat transfer coefficient.

Heat transfer correlations proposed by various authors for the annular film region are summarized in (Section E, Table 4.1). The prediction based on Guerrieri & Talty⁽⁴⁸⁾ correlation is rather poor and Dengler & Addams⁽¹¹⁾ correlation is applicable to forced circulation units only. Anderson et.al.⁽¹⁴⁾ theoretical analysis can be used but requires a rigorous computational procedure. Kunz⁽¹⁹⁾ theoretical analysis has not been substantiated by adequate experimental

data. Penman & Tait⁽¹⁶⁾ correlation is based on the use of two dimensionless groups and has been shown to fit very well with their experimental data and compare favourably with the predictions from Anderson et.al.⁽¹⁴⁾ theoretical approach. Hence correlation proposed by Penman & Tait can be used to simulate the heat transfer in the annular film region of a LTV evaporator tube.

A summary of the heat transfer correlations based on the above review for simulating heat transfer phenomena in a LTV evaporator tube is given below:

1. Convective Heat Transfer to Single Phase Liquid (Non boiling Region) -

Badger et.al.⁽⁶⁾

$$U_{NB} = 0.06 \left(\frac{C \Delta T_{NB} \rho^2}{\mu_{NB}} \right)^{0.7} \quad (4.1)$$

U_{NB} = Overall heat transfer coefficient for non boiling section, BTU/hr sq ft. °F

C = Specific heat of liquid, BTU/lb °F

ΔT_{NB} = Mean temperature difference for non boiling section, °F

ρ = Density of liquid, lb-m/cu.ft.

μ = Viscosity of the liquid lb/ft. hr.

2. Nucleate Boiling Heat Transfer Coefficient - Coulson & McNelly⁽¹⁰⁾

Low heat flux equation:

$$Nu = (1.3 + 39d) Pr_L^{0.9} Re_L^{0.23} Re_V^{0.34} \left(\frac{\rho_L}{\rho_V} \right)^{0.25} \left(\frac{\mu_V}{\mu_L} \right) \quad (4.2)$$

Where

$$\text{Nu} = \frac{h_B d}{k_L}, \quad \text{Pr}_L = \frac{C \mu_L}{k_L}$$

$$\text{Re}_L = \frac{4 W_f}{d \cdot \mu_L \cdot \pi}, \quad \text{Re}_V = \frac{Q \cdot L}{\lambda \cdot \mu_V} = \frac{4 W_V}{\pi d \mu_V}$$

High heat flux equation:

$$\frac{h_B d}{k_L} = 0.225 \left(\frac{C \mu_L}{k_L} \right)^{0.69} \left(\frac{Q \cdot d}{\lambda \cdot \mu_L} \right)^{0.69} \left(\frac{P \cdot d}{J} \right)^{0.31} \left(\frac{\rho_L}{\rho_V} - 1 \right)^{0.33} \quad (4.3)$$

d = Internal dia., ft.

h_B = Nucleate Boiling heat transfer co-efficient, BTU/hr.sq.ft.°F

k_L = Thermal conductivity, BTU/hr ft. °F

C = Specific heat, BTU/lb °F

μ = Viscosity, lb/ft. hr

W_f = Feed rate, lb/hr

Q = Heat flux, BTU/hr sq.ft.

L = Length of the tube, ft.

λ = Latent heat of vaporization, BTU/lb

P = Pressure, lb/sq ft.

ρ = Density, lb/Cu ft.

σ = Surface tension, lb/sq hr

3. Annular film heat transfer coefficient - Penman & Tait⁽¹⁶⁾

$$\frac{h}{C_{PL}} \sqrt{\frac{D}{\rho_L \sigma g_c}} = 0.012 \left[V_v \sqrt{\frac{D \rho_v}{g_c \sigma}} \right]^{0.5} \quad (4.4)$$

Where

h = film heat transfer co-efficient BTU/Sec. sq.ft. °F

C_{PL} = specific heat of liquor, BTU/lb °F

D = Diameter, ft.

ρ = Density, lb-m/cu ft.

σ = Surface tension, lb-f/ft.

V_v = Velocity of vapour, ft/sec.

g_c = Constant, 32.2 lb-m. ft/lbf. sec².

4. Shell - Side Heat Transfer Co-efficient-

The shell side heat transfer co-efficient for the filmwise condensation of steam can be determined from equation 4.5 (McAdams⁽⁵⁰⁾)

$$h = 1.13 \left[\frac{K_f^3 \rho_f^2 g \Delta H}{L \mu_f (T_{SV} - T_S)} \right]^{0.25} \quad (4.5)$$

Where

ΔH = Latent heat of condensation, BTU/lb

g = gravitational acceleration, ft/hr²

L = Length of tube, ft

T_S = Surface temperature, °F

T_{SV} = Saturated vapor temperature, °F

D = Outside diameter of tube, ft.

B. Frictional Pressure Drop & Hold-up Correlations:

Correlations representing frictional pressure drop and hold up are necessary for the prediction of pressure along the length of the evaporator tube length based upon energy, momentum and continuity balances.

Frictional pressure drop in the single phase liquid can be estimated from equations 4.6 - 4.11, given by Knudson & Katz⁽³¹⁾.

$$\Delta P_f = \frac{4f}{D} \frac{LV^2}{2 g_c} \quad (4.6)$$

The effect of roughness characteristics of the tube on the value of friction factor can be determined from equations 4.7, 4.8 and 4.9.

$$\text{For laminar flow : } f = 16/N_{Re} \quad (4.7)$$

$$\begin{aligned} \text{For turbulent flow: } \frac{1}{\sqrt{f}} &= 4 \log \frac{d_w}{e} + 2.28 \quad (4.8) \\ \text{for } \frac{r_w/e}{R_e \sqrt{5}} &> 0.005 \end{aligned}$$

For transitation flow:

$$\frac{1}{\sqrt{f}} = 4 \log \frac{d_w}{e} + 2.28 - 4 \log \left[1 + 4.67 \frac{d_w/e}{R_e \sqrt{f}} \right] \quad (4.9)$$

For the case of nonisothermal flow in pipes, there is small change in the value of friction factor as given by Perry⁽²⁹⁾ and Seider et.al.⁽³⁰⁾. In the case of heating

$$\text{Divide } f \text{ by } (\mu_a / \mu_w)^{0.38} \text{ for laminar region} \quad (4.10)$$

$$\text{Divide } f \text{ by } (\mu_a / \mu_w)^{0.17} \text{ for turbulent region} \quad (4.11)$$

(The units to use in equations 4.6 to 4.11 are as follows:

- D = Tube Dia., ft
 L = Tube length, ft
 ρ = Fluid density, lb/Cu ft
 V = Fluid velocity, ft/sec.
 f = Friction factor
 ΔP_f = Pressure drop due to friction lb_f/sq ft.
 d_w = Tube dia. inch
 r_w = Radius of tube, inch
 μ_a = Viscosity at mean temp., cp
 μ_w = Viscosity at wall temp., cp)

The prediction of pressure drop in the boiling section would involve a detailed consideration of two-phase liquid-vapor flow patterns. Frictional pressure drop & hold-up correlation for the two phase flow have been reviewed by several authors^(21,24,33,34,52-61) and have recommended the use of Lochart & Martinelli⁽²⁴⁾ correlation for two phase frictional pressure drop given by equation 4.12.

$$\left(\frac{\Delta P}{\Delta L} \right)_{\text{fric}} = \left[\frac{2 \left(\frac{4}{\pi} \right)^{2-n} C_1 \mu_1^{1/4} W_1^{2-n}}{D_p^{5-n} \rho_1 g} \right]^{n-2} \left(\frac{D_p}{D_1} \right)^{5-n} \quad (4.12)$$

The calculation of two phase flow pressure drop by Lochart & Martinelli analysis is discussed in Appendix A.

Levy⁽⁶²⁾ correlation can be used to predict the hold-up for

the flow of air water & liquid-vapor mixtures in vertical pipes.

$$\frac{(1-X)^2}{1-\alpha} + \frac{X^2 f_L}{\alpha f_G} - \frac{(1-X)^2}{2(1-\alpha)^2} = 0 \quad (4.13)$$

Where X = Quality of vapor

α = Vapor volume fraction

f_L = Density of liquid

f_G = Density of vapor

C. Engineering Properties of Process Liquors:

The use of momentum, continuity and energy, frictional pressure drop, hold-up & heat transfer correlation for the simulation of long tube vertical evaporator requires a compilation of the engineering properties and characteristics of commercial process liquors. These properties include density, viscosity, specific heat, thermal conductivity, surface tension, boiling point elevation and vapor pressure data. This study deals with the evaporation of black liquors from alkaline pulping processes. Paper industries in India use bamboo as the main cellulosic raw material. Other fibrous raw materials used in current practice include mixed hard-woods, baggase, grasses, straws, salai and pinewood; the use of these raw materials is rather limited and is determined by their availability to the paper mills. It is hoped that in the next four-five years the use of eucalyptus will be gradually established as a important pulping raw material. Several mills use bamboo as the major raw material and meet the balance of their requirements from same or the other cellulosic raw materials listed above. These raw materials are normally pulped separately owing to diverse differences in their physical,

chemical and morphological properties. The spent liquors from these pulping operations are usually mixed and treated for chemical recovery. The weak black liquor contains 12-22% dissolved solids; approximately two-thirds of the black liquor solids are organic compounds dissolved from the fibrous raw material during alkaline pulping reactions. The remaining one third portion of the black liquor solids constitute the spent inorganic chemicals. The organic compounds include lignin and carbohydrate degradation products, and are dissolved in black liquor as their sodium salts. Other organic compounds include soaps (sodium salt of resin and fatty acids present in the wood). This often leads to foam problems during handling of weak black liquors. The inorganic compounds in the black liquor include residual sodium hydroxide, sodium sulfide, sodium carbonate and smaller amounts of sodium sulfate, sodium thiosulfate, sodium sulfite etc. Black liquors from the pulping of bamboo, bagasse and agricultural residues usually contain a appreciable concentration of silica as sodium silicate in solution. This usually leads to scaling problems in chemical recovery equipments requiring frequent shutdowns for maintenance, when the weak black liquor is concentrated to 45-50% solid concentration in multiple LTV evaporators consisting of 5-7 effects. The concentrated black liquor is subsequently burnt in the recovery boilers for reclaiming pulping chemicals and to utilize calorific value of the organic compounds in the black liquor solids.

Even though bamboo is a major raw material in use today, it is possible that substantial quantities of bagasse from sugar mill and eucalyptus from plantation may become available to the paper industry. Such a situation would then require that a given pulp mill be in a position

to handle two or more major fibrous raw materials. The chemical recovery units must be capable of handling the black liquors from different fibrous sources. Koorse⁽³⁸⁾ has demonstrated the diverge differences in some of the engineering properties specially viscosity of bamboo, baggase and eucalyptus black liquors.

We can foresee a condition in the next few years when a particular paper mill will be handling bamboo for five to six months and baggase for the rest of the year. It would be possible to predict the changes in the evaporation plant on switching from bamboo to baggase using the simulation programme of this investigation. This would however require numerous engineering data for bamboo and baggase black liquors. The latter information has been experimentally obtained using commerical bamboo and baggase black liquors from Indian paper mills by Koorse⁽³⁸⁾. Correlations for the engineering properties of the liquors are summarized below:

1. Properties of Bamboo Black Liquor - Koorse⁽³⁸⁾

Viscosity: $\mu = \text{Exp} (A + B.S + C.S^2 + D.S^3)$, cp (4.14)

Where

$$A = 4.4014 - 0.2248 T + 0.0018 T^2$$

$$B = -0.479 + 0.0296 T - 0.00025 T^2$$

$$C = 0.02075 - 0.0013 T + 0.00001 T^2$$

$$D = -0.000175 + 0.00015 T - 0.0000001 T^2$$

Density: $\rho_L = 1.0182 + 0.00779 S - (0.000219 + 0.000003 S) \cdot T$, g/cc
(4.15)

Thermal Conductivity: $k = 0.53354269 - 0.003425 S + (0.0011355 + 0.00000209 S)T$
KCal/hr. m°K (4.16)

$$\text{Boiling point Elevation: B.P.E.} = 0.19 S, ^\circ\text{C} \quad (4.17)$$

Equation 4.17 for boiling point rise was obtained from limited experimental data and hence needs further refinement with additional data. Nevertheless it can be used as an approximate expression to include the effect of boiling point rise in the evaporator calculations.

2. Properties of Bagasse Black Liquor - Koorse⁽³⁸⁾

$$\text{Viscosity: } \mu = \text{Exp} (A + B.S + C.S^2), \text{ cp} \quad (4.18)$$

$$\text{where } A = 18.276186 - 0.507619 T + 0.00343 T^2$$

$$B = -1.427423 + 0.043054 T - 0.0003074 T^2$$

$$C = 0.032877 - 0.00898 T + 0.0000064 T^2$$

$$\text{Density: } \rho_L = 1.0207 + 0.0071 S - T (0.000279 + 0.0000012 S) \text{ g/cc} \quad (4.19)$$

$$\begin{aligned} \text{Thermal Conductivity: } K &= 0.050579 - 0.002563 S + (0.000899 + 0.00000749) S \\ &\text{KCal/hr.m}^\circ\text{K} \quad (4.20) \end{aligned}$$

$$\text{Specific Heat: } C_L = 0.993 - 0.01258 S + (0.0000556 + 0.000104 S) \quad (4.21)$$

$$\text{Boiling Point Elevation: B.P.E.} = 0.14 S, ^\circ\text{C} \quad (4.22)$$

Equation 4.22 can be used as an approximate expression to include the effect of boiling point rise in the evaporator calculations.

3. Properties of Pinewood Black Liquor - Gudmundson⁽³⁵⁾

$$\text{Viscosity: } \mu = \text{Exp} (A + B.S + C.S^2 + D.S^3), \text{ cp} \quad (4.23)$$

$$\text{Where } A = 0.4717 - 0.02472 T + 0.7059 \times 10^{-5} T^2$$

$$B = 0.06973 - 0.5452 \times 10^{-3} T + 0.1656 \times 10^{-5} T^2$$

$$C = 0.002046 + 0.3183 \times 10^{-3} T - 0.9761 \times 10^{-7} T^2$$

$$D = 0.5793 \times 10^{-4} - 0.6129 \times 10^{-6} T + 0.1837 \times 10^{-8} T^2$$

$$\text{Density: } \rho_L = 1007 - 0.495 T + 6.0 S, \text{ Kg/m}^3 \quad (4.24)$$

$$\text{Specific Heat: } C_L = (1.0 - 0.0054 S) 0.4187, \text{ WS/Kg } ^\circ\text{K} \quad (4.25)$$

4. Properties of Water -

$$\text{Viscosity: } \mu = 1.996531 - .0160284 T + .00006745 T^2, \text{ cp} \quad (4.26)$$

$$\text{Thermal Conductivity: } K = 587(1 + 0.00281 (T - 20)) 2.389 \times 10^{-6} \text{ Cal/cm.sec. } ^\circ\text{C} \quad (4.27)$$

5. Vapor Pressure-Temperature Relationship -

Vapor pressure and temperature can be correlated by Antoine equation 4.26 or 4.27

$$\log_{10} P = A - \frac{B}{T - \text{B.P.E.} + C} \quad (4.28)$$

$$T = \frac{B}{A - \log_{10} P} - C + \text{B.P.E.} \quad (4.29)$$

Values of Antoine equation constants are given in Table C-1 & C-2 of Appendix C respectively for equation 4.26 and 4.27.

(The units to use in equations 4.14 to 4.27 are as follows

P = Pressure, mm of Hg.

T = Temperature, $^\circ\text{C}$

S = Solid concentration, wt %)

CHAPTER 5

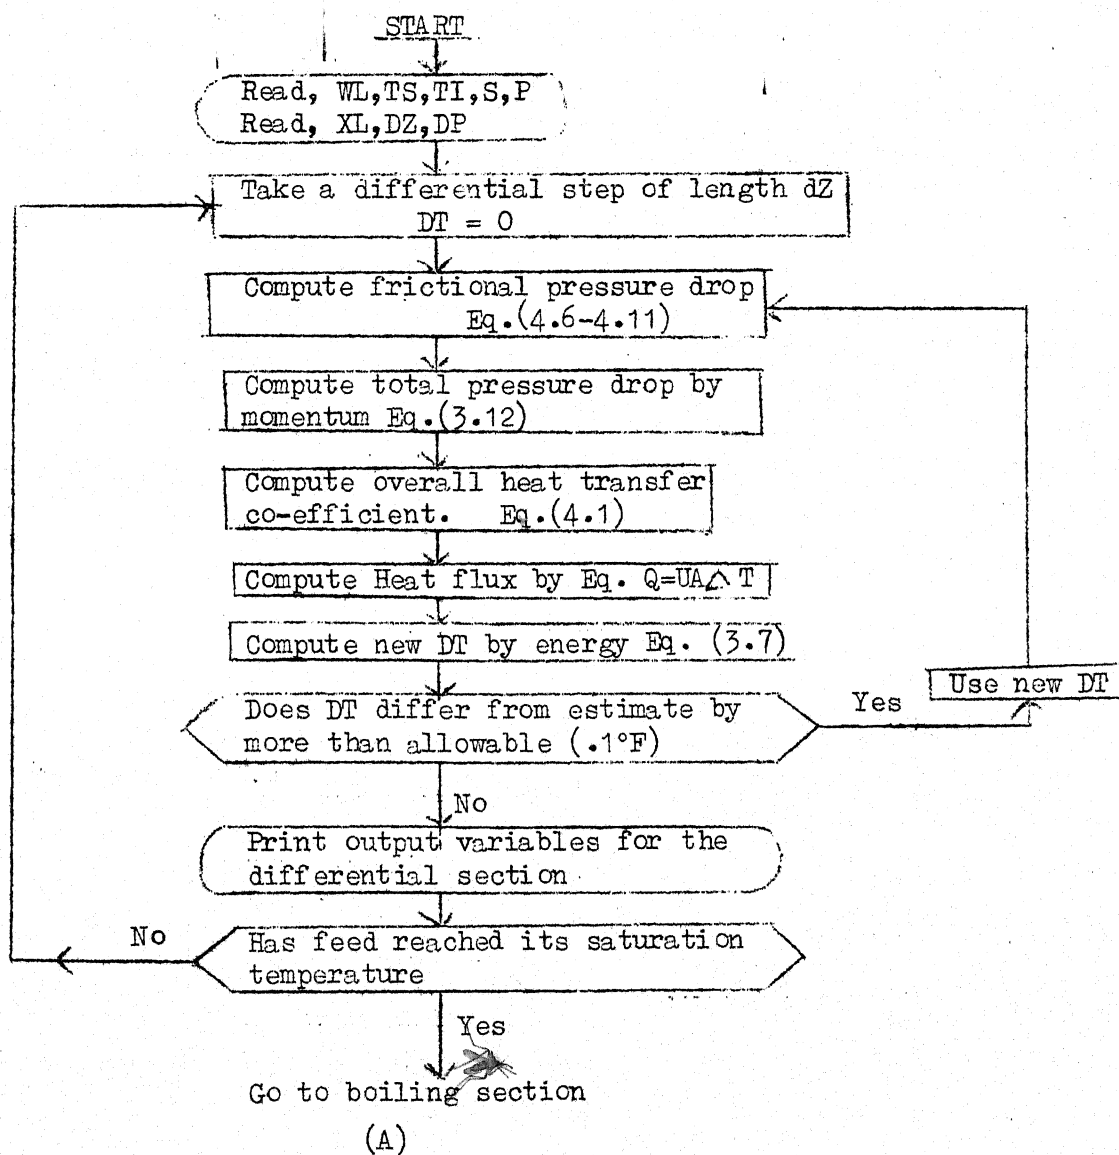

COMPUTATIONAL SCHEME FOR LONG TUBE VERTICAL EVAPORATOR

In simulating the performance of a LTV evaporator, process feed liquor conditions such as liquor flow rate, concentration of solids, temperature and pressures are usually available. Simulation consists in predicting the profiles of liquor temperature, concentration, heat flux and overall heat transfer co-efficient along the length of the evaporator tube. These computations would also give variation in pressure, pressure gradient, void fraction and vapor quality along the tube length. Computations would begin with the feed inlet conditions at the bottom of the evaporator tube and proceed through the nonboiling, nucleate boiling and annular film regions, and thus traverse the entire tube length.

Simulation computations are carried out in a stepwise manner assuming a series of differential sections of the evaporator tube and using the criteria of a maxima in liquor temperature profile and a minima in the pressure gradient curve for the transition from nonboiling to nucleate boiling and from nucleate boiling to annular film region respectively.

For a weak black liquor feed below its saturation temperature, flow chart of computation for the nonboiling section is given in Figure 5.1. Flow rate, concentration, temperature and pressure of feed liquor, steam chest temperature and tube geometry are fixed for starting the calculations. A differential length dZ of tube (.15 meter) is considered to determine the heat transfer rates. The liquor temperature in this differential section is assumed to be isothermal at first. The change in pressure in this section

Fig. 5.1 Flow Diagram for Nonboiling Section of a LTV Tube

can be calculated from the frictional pressure drop correlation equations (4.6 - 4.11) and momentum balance equation (3.12). The overall heat transfer co-efficient for nonboiling section can be obtained by Badger correlation equation 4.1. Heat flux can be computed by the heat transfer rate equation ($Q = UA\Delta T$). The next step consists of determining differential change in the temperature by energy equation 3.7. This new value of DT is then compared with the previously assumed value for the start of the computations. If they differ by more than a certain specified limit (.1 °F), then the calculations are repeated with this new value of DT . In case the difference is within specified limit then the calculated liquor temperature is compared with the saturation temperature corresponding to the estimated pressure at the exit of the differential section. If the liquor temperature happens to be below the saturation temperature, the calculations are repeated for the next differential section. This iterative procedure is repeated for several differential sections until the liquor temperature equals the saturation temperature of liquor. This point corresponds to the end of the nonboiling regime and subsequent calculations are carried out for the boiling section.

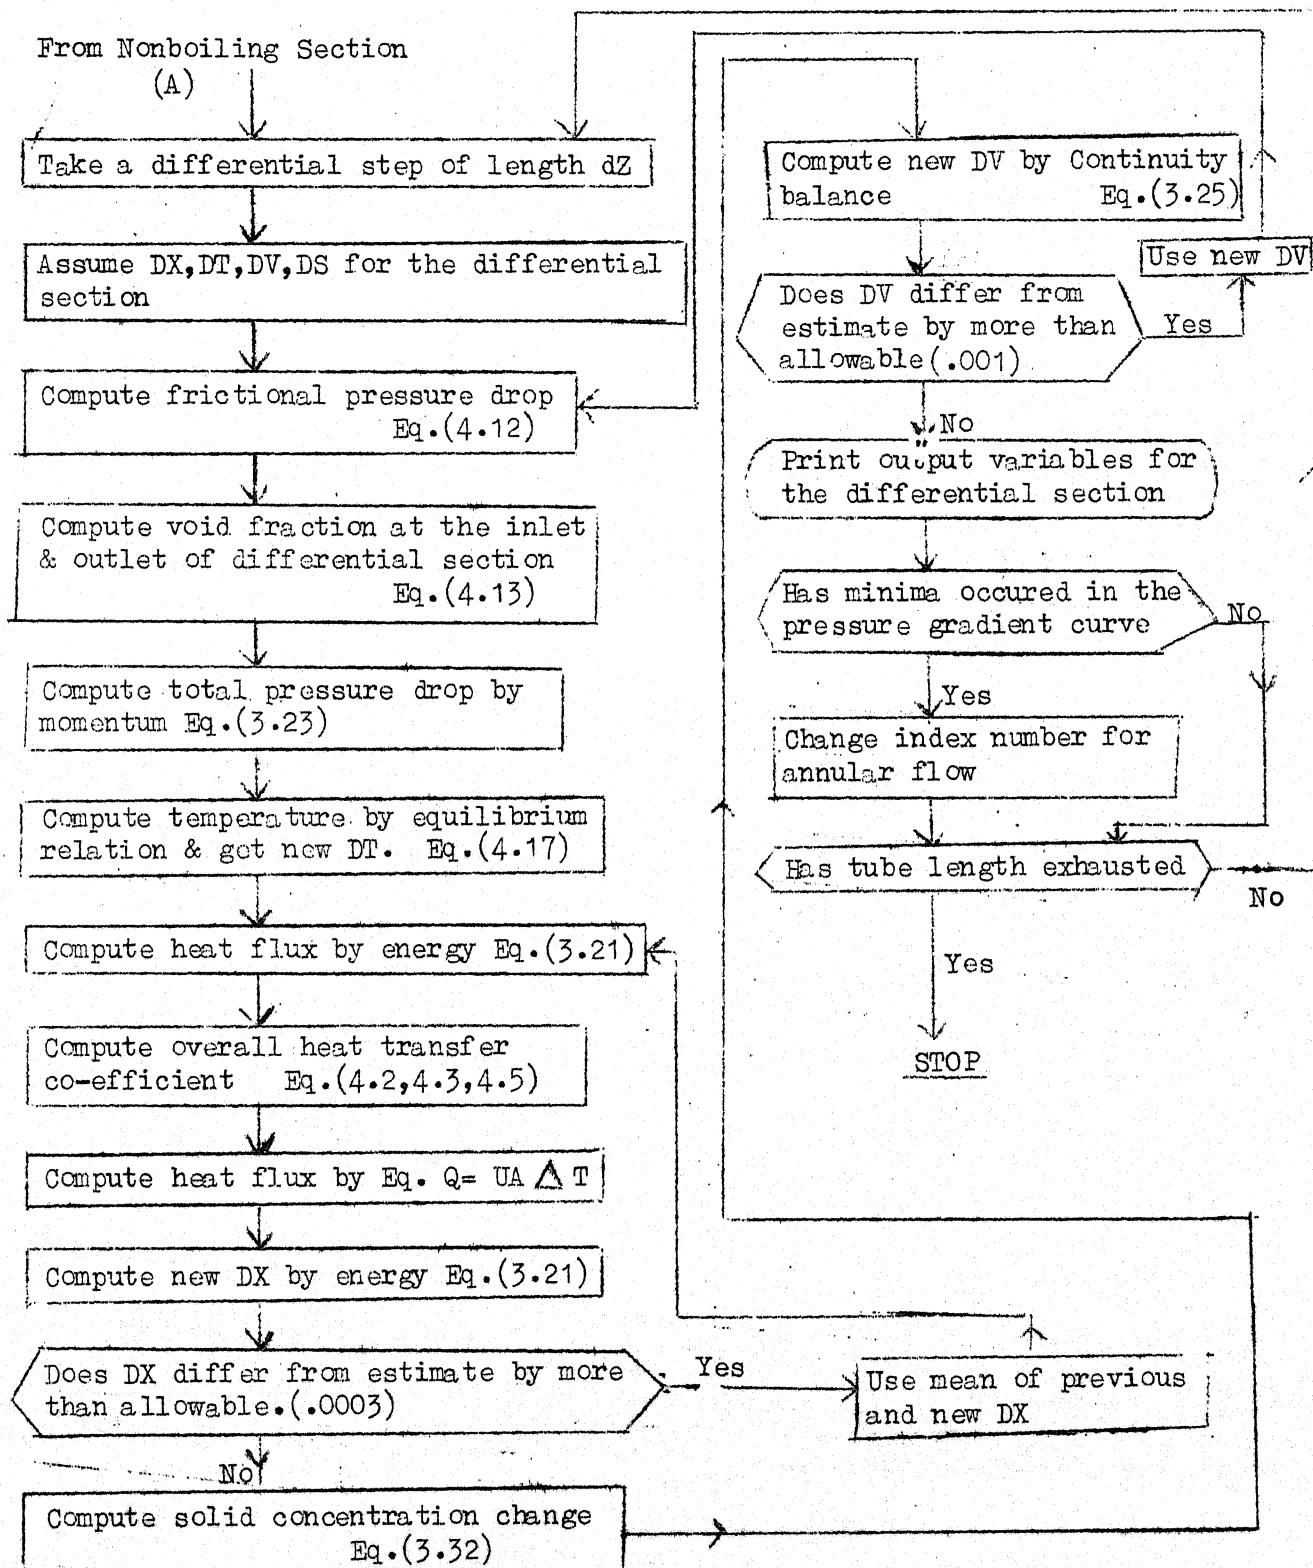

For the boiling section, simulation computations can be performed by assuming either homogeneous model or slip model for the two phase vapor-liquid mixture flow as given below:

1. Homogeneous Model:

Homogeneous model assumes that the velocity of liquid and vapor are same and there is no slip between liquid and vapor. The

computational scheme for estimating changes in the process liquor conditions and heat transfer rate is shown in Fig. 5.2 for the boiling section. Conditions of the liquor feed to the boiling section would be the same as exit liquor conditions from the nonboiling section. Now consider a differential length dZ (0.15 meter) in the evaporator tube length. The calculation for this differential section must give the change in liquor temperature, pressure, pressure gradient, concentration, quality, void fraction, heat flux and overall heat transfer co-efficients. Firstly values for the change in the quality, temperature, solid concentration and velocity (DX, DT, DS, DV respectively) for this differential segment are assumed. Two phase flow frictional pressure drop is calculated by Lockhart and Martinelli correlation (equation 4.12). The void fraction at the inlet and exit of the differential zone can be calculated by Levy correlation (equation 4.13). Obviously the void fraction at the entrance to the boiling section will ^{be} zero and gradually increases as boiling progresses along the evaporator tube. The total pressure drop can be obtained by momentum balance (eq. 3.23). The temperature corresponding to the calculated pressure can be determined from the Antoine eq. 4.17 and this would give new value of change in temperature for the differential section. Heat flux for the differential section can be obtained by the energy equation 3.21. Overall heat transfer co-efficients can be calculated by using eq. 4.2, 4.3 and 4.5. New value of heat flux can be calculated by heat transfer rate equation ($Q = UA \Delta T$). This value of heat flux can be used in energy eq. 3.21 to calculate new value of change in quality for the differential section and is compared with the previously assumed value of DX . If the difference between these two values of DX is

Fig. 5.2 Flow Diagram for Boiling Section (Homogeneous Model) of a LTV Tube

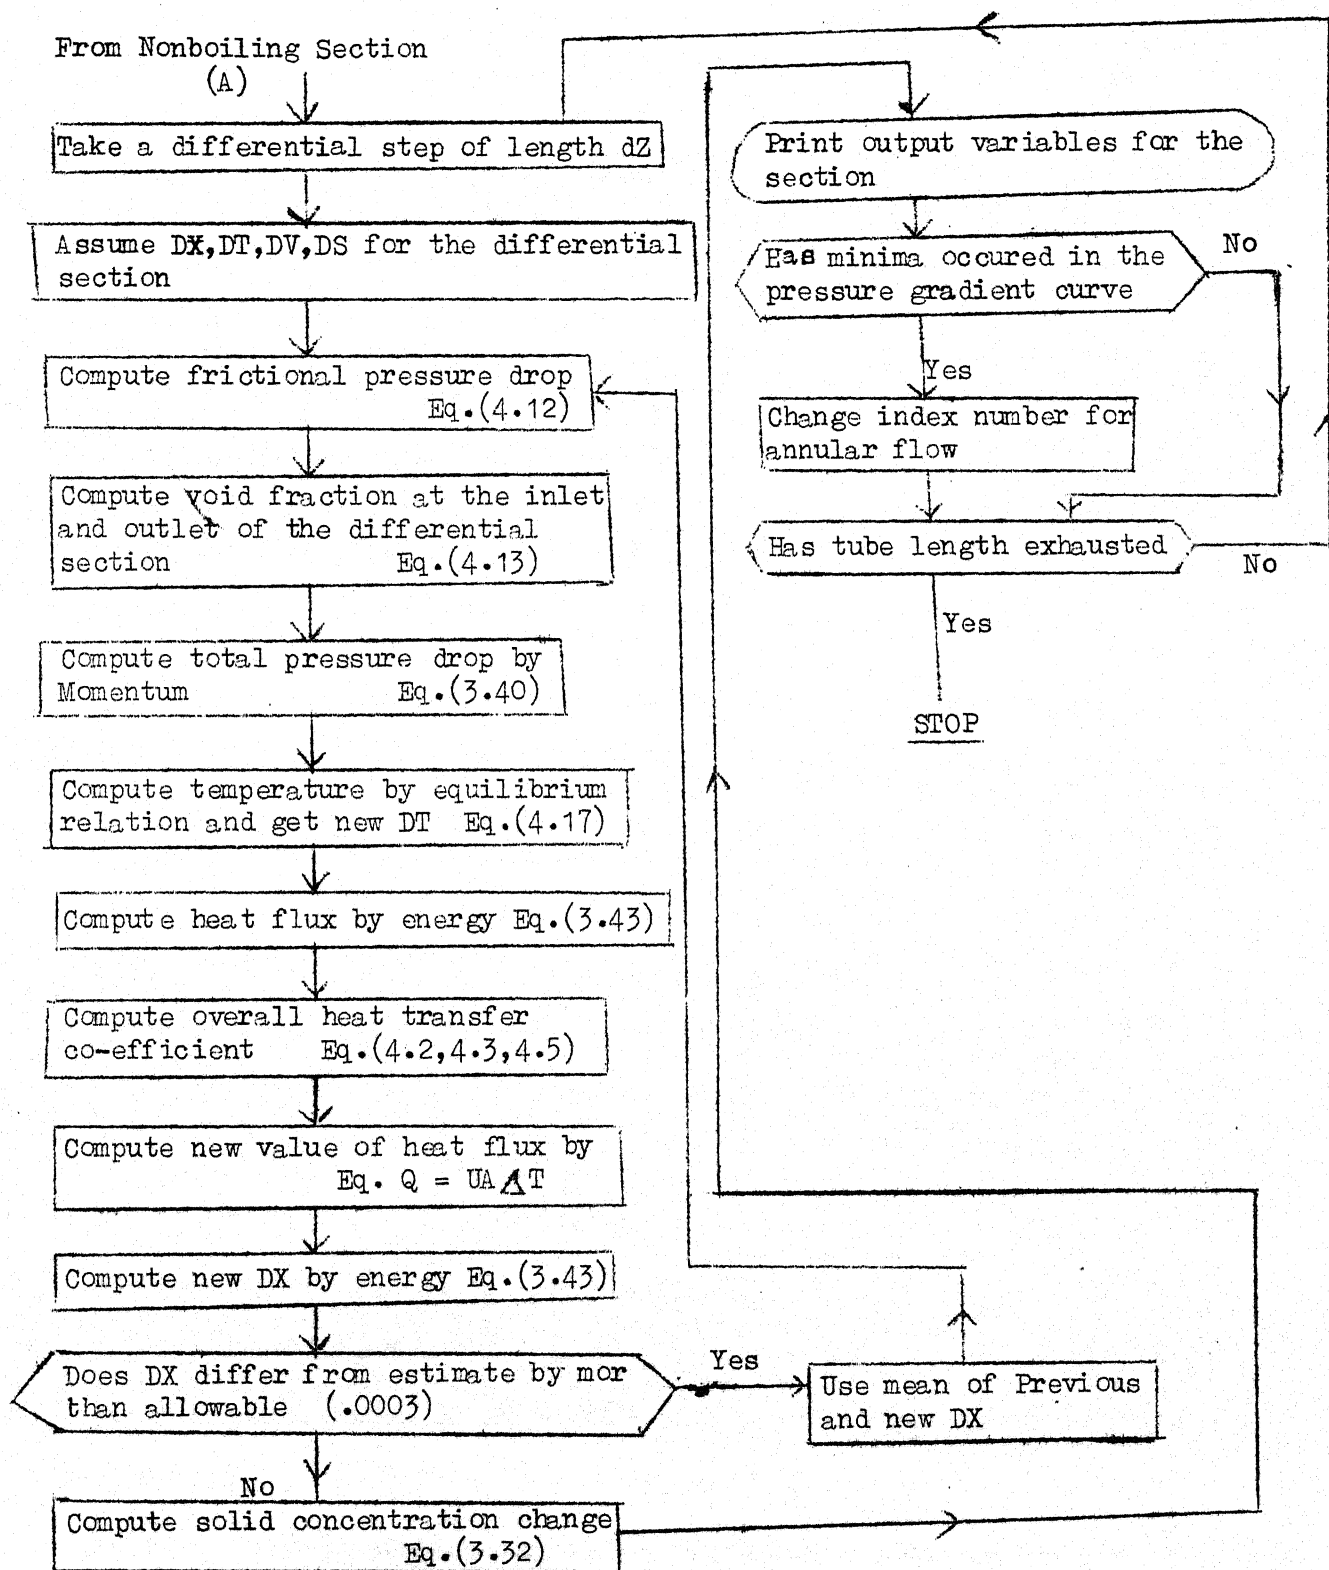

larger than a certain specified limit (.0003) then an average of these two values of quality is used and the calculations are repeated from the step computing heat flux from energy eq. 3.21 until the difference between calculated and the assumed values of DX is within specified limit. In case difference is within specified limit, solid concentration change is obtained by eq. 3.32. Now value of change in the velocity of homogeneous phase can be calculated by continuity eq. 3.25 and can be compared with the previously assumed values of DV . If the difference between these two values is larger than a certain specified limit (.0003 meter/sec) than calculations are repeated with this new value. In case difference is within specified limit, pressure gradient curve is checked for the minima. Index number which will make change from nucleate boiling to annular film flow will be changed with the occurrence of minima in the pressure gradient curve. This iterative procedure is carried out for several differential sections until whole of the length is traversed.

For annular flow region, computational procedure is same as for nucleate boiling region except Penman and Tait eq. 4.4 of annular film heat transfer co-efficient is used in place of eq. 4.2 & 4.3.

Slip Model:

Slip model implies a different velocity for liquor and vapor phases. Flow chart for the simulation of heat transfer and other phenomena based on slip model is given in Fig.5.3. This scheme of computation based on slip model is essentially the same as for homogeneous model except with a slight difference that eq. 3.40 and 3.43 are used to estimate pressure drop and temperature change respectively for the differential section.

Fig. 5.3 Flow Diagram for Boiling Section(Slip Model) of a LTV Tube

CHAPTER 6

RESULTS & DISCUSSION

The computational scheme outlined in chapter 5 is used to simulate the long tube vertical evaporator for the following liquor systems: water, bamboo black liquor, ~~bagasse~~ black liquor and pinewood black liquor.

Single Effect LTV Evaporation Simulation:

A. Application of Simulation Models to Badger's Data for Water:

The accuracy of the simulation programme for single effect evaporator calculations has been compared with the experimental data of Brooks and Badges⁽⁴⁾ for the evaporation of water in a LTV unit consisting 6.1 meter long and 5.08/4.45 Cm diameter tube. Brooks and Badges's experimental data for water are summarized in Table 6.1. The variation in process variables along the tube length is determined by the simulation programme based on flow charts Fig. 5.1 and Fig.5.2 for nonboiling and boiling section (Homogeneous model) respectively. The length of the boiling section and the corresponding rates of evaporation and heat transfer, and the average overall boiling heat transfer co-efficient ($A_{o3} U = \sum U_i \Delta T_i / \sum \Delta T_i$) obtained from the simulation programme given in Table 6.2 for the experiments reported by Brooks and Badger. Brooks and Badger's results are also included in Table 6.2 for comparison purposes. The range and average percent deviation

% Deviation	-19.6	101.0	-5.0	0.5

(Table 6.2 continued)

Computed value	4.04	91.5	22.94	3.15
6 Experimental value	4.91	59.5	37.50	3.34
% Deviation	-19.5	54.0	-39.1	-5.6
Computed value	4.25	79.5	21.44	3.17
7 Experimental value	5.12	54.6	34.66	3.25
% Deviation	-17.1	46.5	-38.3	-2.54
Computed Value	4.58	74.2	21.70	3.14
8 Experimental value	5.45	56.5	35.60	3.24
% Deviation	-16.2	32.0	-39.8	-2.8
Deviation range %	14-20	32-101	5-50	0.5-12
% Average Deviation	17.2	53.9	33.9	6.2

of the calculated values from the Brooks and Badger's experimental observations are given below (assuming homogeneous model for the boiling section):

<u>Process Variables</u>	<u>Deviation range, %</u>	<u>Average Deviation, %</u>
Boiling section length	14-20	17
Evaporation rate	32-101	54
Heat Transfer rate	5-50	34
Boiling average overall		
heat transfer co-efficient	2-12	6

The above results show that while this simulation model can predict the overall heat transfer co-efficient quite well, accuracy for predicting the boiling length can be considered moderate and the estimates of the rate of evaporation and heat transfer by the model are poor. The rather large deviations observed may be attributed to the limitations imposed by the homogenous model which assumes equal velocity for the gas and liquid phases during two phase flow.

The slip model for the boiling section was then used to simulate the process conditions of Brook & Badger's experiments based on flow chart 5.1 & 5.3. Results as obtained by using this model and Badger's experimental results are given in Table 6.3 which also include % deviation of the predicted values from the experimental values. The following observations can be made from the results in Table 6.3, concerning the accuracy of the simulation programme based on slip model for two phase

Table 6.3 Simulation results for Water Evaporation Using Slip Model:

Data	Boiling Section Length (Meter)	Evaporation Rate (Kg/hr)	Heat Transfer rate in the boiling Section(KW)	Average overall Heat transfer Co-efficient in Boiling Section (KW/m ² °K)

flow:

<u>Process Variables</u>	<u>Deviation range, %</u>	<u>Average Deviation, %</u>
Boiling section length	4 - 20	15.2
Evaporation rate	8 - 19	13.2
Heat Transfer rate	6 - 20	13.1
Boiling average overall		
heat transfer co-efficient	10 - 22	17.2

The above results show that the simulation programme of this study assuming slip model can predict Brooks and Badger's experimental conditions with an overall accuracy of about 15%. Hence the simulation programme based on flow charts 5.1 and 5.3 for the nonboiling and boiling section (slip model for two phase flow) respectively ~~can be used~~ for the subsequent calculations of this investigation for evaporation of bamboo, baggase and pinewood black liquor from alkaline pulping processes.

B. Comparison with Gudmundson's Experimental curves:

The simulation programme is also used for comparing the predicted values with the experimental results of Gudmundson^(2,45). The evaporator used in the latter work consisted of four 10 m long stainless steel tubes with diameters of 51/46 mm. Gudmundson's results for water at a feed rate of 18 Kg/Sm² are used in this comparison.

Figures 6.1, 6.2 and 6.3 give the predicted temperature profile and overall heat transfer Co-efficient along the tubelength for the various inlet feed temperatures of 76°C, 81.5°C and 85°C; and corresponding steam temperatures of 91.5°C, 95°C and 86.5°C. The simulation calculations are represented by the continuous curves in the above figures assuming slip model for the two phase flow region. The predicted temperature

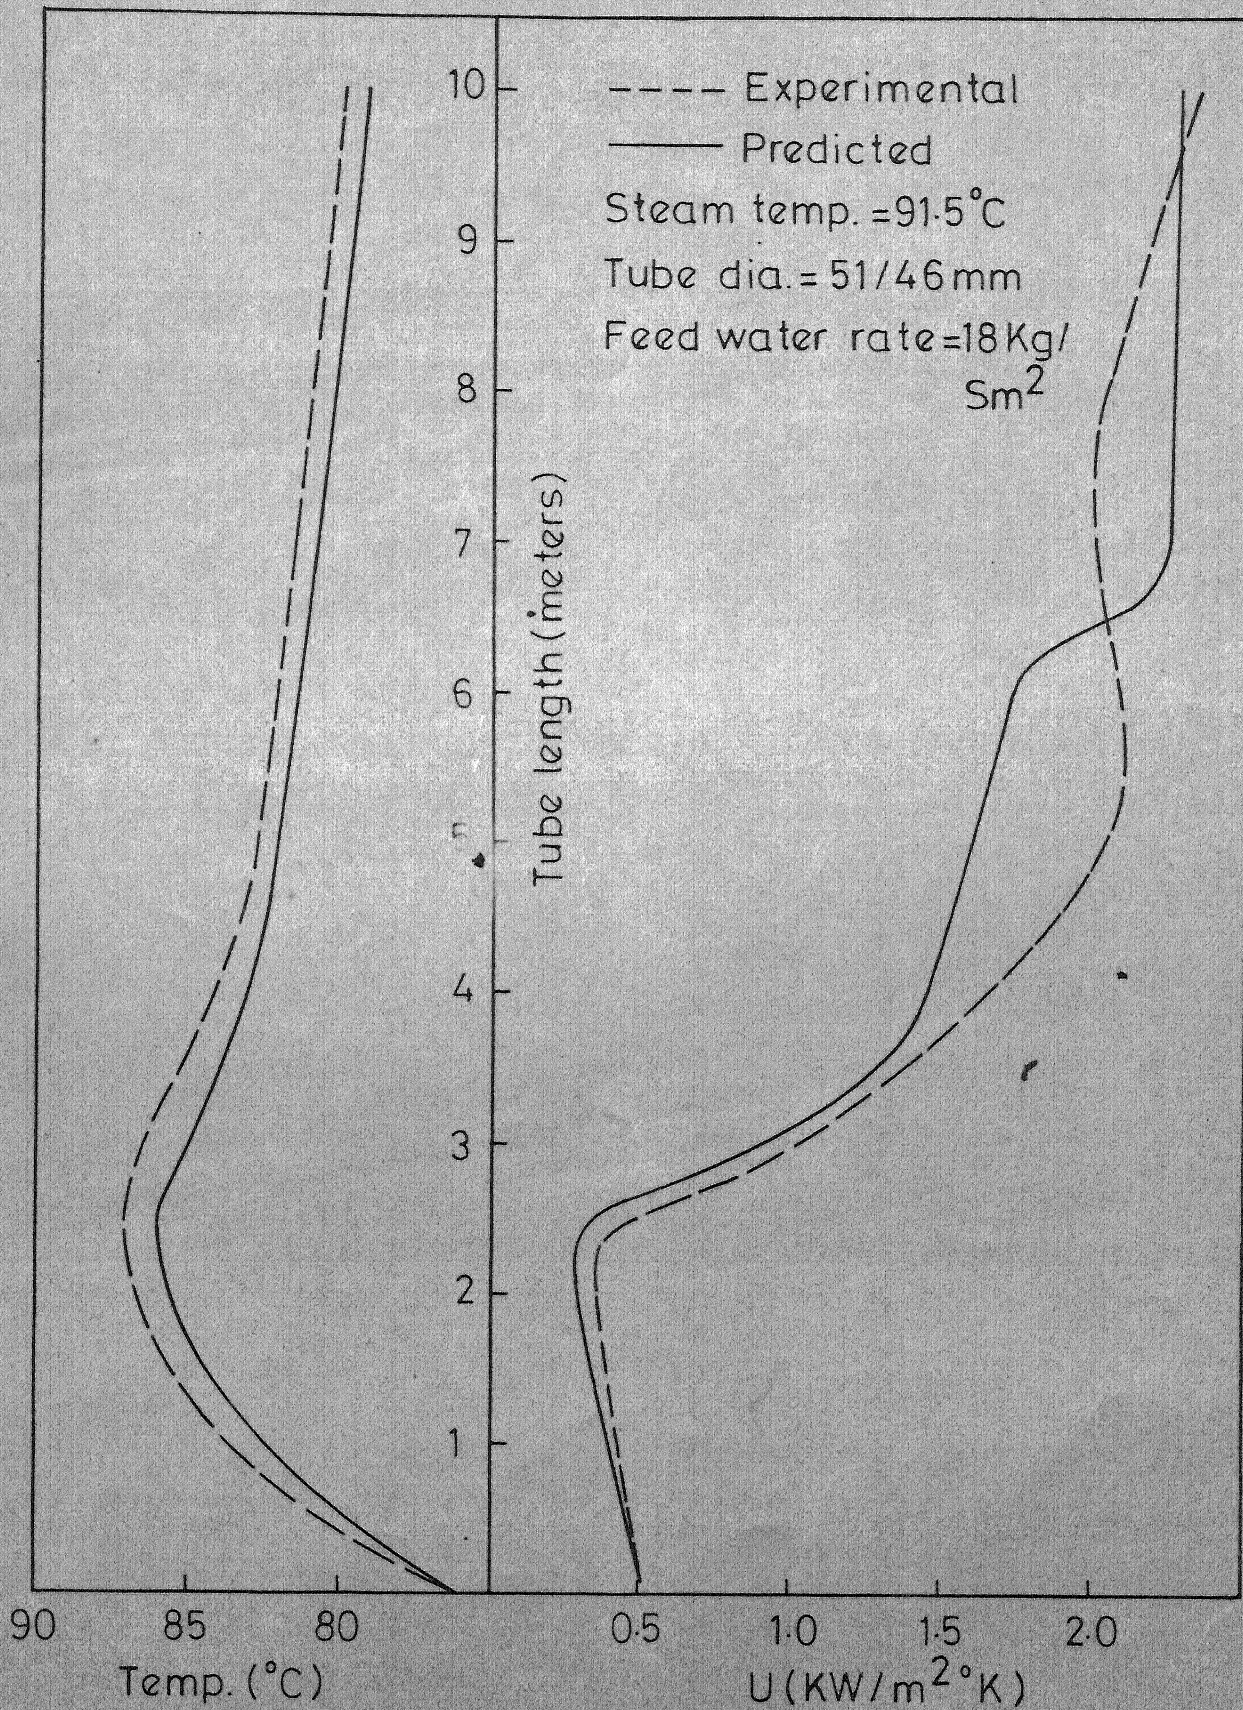

Fig.6.1 - Comparison of predicted values with experimental data for water.

Fig.6.2 - Comparison of predicted values with Gudmundson's experimental data for water.

Fig.6.3 - Comparison of predicted values with Gudmundson's experimental data for water.

profiles agree with the experimental data quite well; the agreement is within 1°C for the two sets of data represented in figures 6.1 and 6.3 and is within 2°C for the data in Figures 6.2. Experimental curves for the over all heat transfer co-efficient deviates somewhat from the predicted profiles based on this study. Experimental results in general show an average deviation of about 25% from the predicted results.

The above comparisons for the heat transfer of LTV evaporator show that the simulation model of this investigation can be used to predict reliable values of heat transfer rates. Hence the simulation programme based on flow charts Fig. 5.1 and 5.3 for the nonboiling and boiling section (slip model for two phase flow) respectively are used for the subsequent calculations of this investigation for evaporation of bamboo, bagasse and pinewood black liquors.

C. Evaporation of Pinewood Black Liquor:

Weak black liquor from the Kraft pulping of pine is assumed to contain 12.0% dissolved solids with a flow rate of 100 tons/hr at a temperature of 50°C . The LTV evaporator unit is arbitrarily assumed to consist of 300 tubes, 5.08 / 4.45 cm dia. and 7.6 meters long. Steam chest pressure is taken to be 306 KN/sq.m. Pressure of the liquor feed is assumed to be 104 KN/sq m. A print out of the simulation programme for the evaporation of pinewood black liquor is given in Appendix D-1 for the representation of homogenous model describing two phase flow pattern. Physical property correlations reported by Cudmundson⁽³⁵⁾ are used in this analysis.

The simulation programme gives the output variables in the following order- vapor quality, void fraction, pressure gradient, pressure, temperature, heat flux, overall heat transfer co-efficient and solid concentration. The variations of these variables along the length of the evaporator tube are shown in Fig. 6.4 - 6.11¹ respectively. It can be observed that of the total length of the evaporator tube (7.6 meter), about 2 meter is used in raising the feed liquor to its boiling point in the non-boiling region.

Fig. 6.4 shows the variation in vapor quality (mass fraction of vapor in the total vapor -liquid mixture flow) along the tube length. It can be seen that the mass fraction of vapor increases from zero at the start of the boiling section to 0.35 and 0.22 towards the end of tube assuming homogeneous and slip models respectively. The difference observed between the two models is caused by the contribution of the kinetic energy terms (eq.3.43). In the homogeneous model kinetic energy is based on the use of homogeneous phase velocity whereas the slip model takes into account the contribution to kinetic energy as terms representing vapor and liquid velocities during two phase flow.

Fig. 6.5 gives the changes in void fraction along the tube and it can be seen that the start of nucleate boiling section is accompanied by a steep increase in void fraction caused by rapid rate of nucleation and bubble coalescence. The homogeneous and slip models give essentially the same value for void fraction. Void fraction at the end

Fig.6.4- Variation of vapor quality along tube length.

Fig. 6.5- Variation of void fraction along tube length.

Fig.6.6-Variation of pressure gradient along tube length.

Fig.6.7- Variation of pressure along tube length.

Fig. 6.8 - Variation of liquor temperature along tube length.

Fig.6.9-Variation of heat flux along tube length.

Fig.6.10-Variation of overall heat transfer co-efficient along tube length.

Fig.6.11 - Variation of liquor concentration along tube length.

of the evaporator tube is in the range of 0.95 - 0.97.

Change in the pressure gradient along the tube length is given in Fig. 6.6. Pressure gradient decreases slightly in the nonboiling section and subsequently rapidly in the boiling section. The observed decrease in the pressure gradient is due to static and frictional pressure drop effects. The lower value of the pressure gradient for the homogeneous model can be attributed to the fact that in homogeneous model, changes in the momentum of fluid is based on the use of homogeneous phase velocity whereas the slip model takes into account the vapor and liquid velocities during two phase flow to calculate change in the momentum of fluid. In the upper portion of the tube pressure gradient becomes substantially constant for the homogeneous model whereas it passes through a minima in the slip model which can be attributed to increasing frictional pressure drop in the annular film region. This minima in the pressure gradient corresponds to transition from nucleate boiling to annular film region. The pressure gradient curve for the slip model is similar to experimental results reported by Anderson et.al⁽¹⁵⁾.

Fig. 6.7 shows a gradual decrease in pressure and is caused by static and frictional pressure drop contributions. The steady decline in pressure in the nonboiling section is due to static pressure drop. In the boiling section pressure decreases at a lower rate due to combined effects of hydrostatic head and frictional losses. The curves in Fig. 6.7 are similar to experimental curves reported by Anderson et.al.⁽¹⁵⁾.

Fig. 6.8 shows variation of liquor temperature in the tube length. It can be seen that less than one third of the evaporator tube length is used in raising the feed from 50°C to 102.5°C (saturation temperature corresponding to the pressure in the tube) in the nonboiling section. In the boiling section extending over more than two thirds of the evaporator length. The homogeneous model and slip model for the two phase flow predict liquor temperature within 3°C of each other.

Heat flux along the tube length is given in Fig. 6.9 and the values predicted by the homogeneous and slip model are nearly equal. The decrease in the value of heat flux for the nonboiling section is caused by the decrease in temperature driving force as the liquor is being heated to its boiling point. The increasing trend in heat flux over the boiling section is due to the increase in overall heat transfer co-efficient for the nucleate boiling and annular film regions. The transition from nucleate boiling to annular film region occurs at 4.3 meter and 5.5 meters from the results of heat flux for the homogeneous and slip models assumptions respectively.

Fig. 6.10 gives the variation of overall heat transfer co-efficient along the tube length and shows clearly the three dominant heat transfer mechanisms in a LTV evaporator tube. Out of a total of 7.6 meters long tube the nonboiling, nucleate boiling and annular film regions extend over 2.0, 2.3 and 3.3 meters respectively for the homogeneous model and the corresponding lengths for the slip model are 2.0, 3.5, 2.1 meters. The transition from nonboiling to nucleate boiling and nucleate boiling

to annular film regions are accompanied by a pronounced increase in the value of overall heat transfer co-efficient. In general the homogeneous model predicts higher value for overall heat transfer co-efficient compared to the value based on the slip model. It can be attributed to the higher value of vapor quality for the homogeneous model which results in higher vapor velocity and this leads to higher heat transfer co-efficient than the slip model (eq.4.2,4.3& 4.4).

Fig. 6.11 gives the change in liquor concentration along the tube length and predicts an increase from a initial concentration of 12% to 18.4% and 15.4% at the tube exit end for the homogeneous and slip models respectively. The higher concentrations observed for the homogeneous model is due to the higher value of overall heat transfer co-efficient obtained in Fig.6.10 compared to slip model.

D. Evaporation of Bamboo Black Liquor:

The simulation programme following the flow charts in Fig. 5.1 and 5.3 based on the slip model for two phase flow is used for the evaporation of bamboo black liquor in a single effect LTV evaporator. Physical property correlations reported by Koorse⁽³⁸⁾ are used in these calculations. Evaporator dimensions and process conditions are chosen to be the same as that used for pinewood black liquor in section C earlier. Two cases of evaporation are assumed for the calculations namely (1) clean tube (2) tube with a dirt resistance of $0.45 \text{ m}^2 \text{ }^\circ\text{K/KW}$. The dependence of the variable on tube length is given in Fig.6.12-6.19 for vapor quality, void fraction, pressure gradient, pressure, temperature, heat flux overall heat transfer co-efficient and solid concentration.

The comparison of the curves 6.12-6.19 with those in Fig.6.4-6.11 shows that the nature of the curves are very similar for the evaporation of Bamboo and pine black liquors. It can be seen from Fig.6.12-6.19 that the contribution of the dirt scale resistance is an important factor and significantly reduces the value of solid concentration obtained for the tubes with clean heat transfer surfaces. Dirt scale resistance increases the tube length corresponding to nonboiling region while decreasing the tube length available for boiling region. For the process conditions assumed for the evaporation of black liquor, the nonboiling section prevailing over 1 meter length of clean tube increases to 2 meter when dirt scale resistance is assumed to $0.45 \text{ m}^2 \text{ }^\circ\text{K/KW}$.

Fig. 6.12 gives variation of vapor quality with tube length and it can be seen that the quality increases from zero at the start of the boiling section to 0.55 and 0.23 towards the end of the tube for clean and fouled surfaces respectively. The higher vapor quality obtainable for the clean surfaces suggest that the process liquor can be evaporated to a higher solid concentration for the given length of the tube. Fouled surface have the effect of decreasing the capacity obtainable using cleaner evaporator tubes.

The graph obtained for the void fraction in Fig.6.13 for bamboo black liquor is essentially identical to the curves obtained for pine black liquor in Fig. 6.5 assuming equal dirt resistance in the tube.

Fig. 6.14 gives the variation of pressure gradient along the evaporator tube. For the last part of the tube length value of pressure

Fig.612-Variation of vapor quality along tube length.

Fig 6.13 - Void fraction in fluid flow along tube length.

Fig.6.14- Variation of pressure gradient along tube length.

Fig.6.15- Variation of liquor pressure along tube length.

Fig.6.16- Variation of liquor temperature along tube length.

Fig.6.17- Variation of heat flux along tube length.

Fig.6.18 - Variation of overall heat transfer coefficient along tube length.

Fig.6.19- Variation of liquor concentration along tube length.

gradient is higher for the clean tube in comparison to fouled tube. The curves go through a minima at 2.2 and 5.2 meters for the clean and fouled tubes respectively and these lengths represent the transition from nucleate boiling to annular film regions. The pressure gradient in the annular film region is up to 5 times the value for the fouled tubes having the dirt resistance of $0.45 \text{ m}^2 \text{ }^\circ\text{K/KW}$. Such a condition can cause regions of low absolute pressure in the annular film region which may lead to plugging of tubes.

Fig. 6.15 describes the longitudinal variation of pressure along the tube length based on pressure gradient given in Fig. 6.14.

Fig. 6.16 gives the profile of liquor temperature and shows that the maximum value of $106.0 \text{ }^\circ\text{C}$ for the clean tube and $102.8 \text{ }^\circ\text{C}$ for the fouled tubes. These profiles are similar to these obtained for pine black liquor in Fig. 6.8.

Fig. 6.17 shows that with clean surfaces it is possible to obtain heat flux rates twice those of the fouled tubes with the assumed dirt resistance value.

The value of the overall heat transfer co-efficient decreases by a factor of 2 to 3 with the assumed value of dirt resistance $0.45 \text{ m}^2 \text{ }^\circ\text{K/KW}$ as demonstrated by the graph in Fig. 6.18.

The change in bamboo black liquor concentration in Fig. 6.19 shows that a final concentration of 27.8% and 15.7% can be obtained for the clean and fouled tubes respectively. This points out the need for relatively clean tube surfaces so that satisfactory evaporator capacity

levels can be maintained.

E. Evaporation of Baggase Black Liquor and a Comparison with Bamboo Black Liquor Evaporation:

The computations for the evaporation of baggase black liquors in the single effect LTV unit are identical to the procedure used earlier for pine and bamboo black liquors. The listing of computational procedure for baggase black liquor is given in Appendix D-2 and is based on the same equipment geometry and process feed liquor conditions as used for the other black liquors in this investigation. Fig. 6.20-6.22 gives the profiles of temperature, overall heat transfer co-efficient and solid concentration along the tube length for both clean and fouled tube surfaces. The curves marked C-2 and D-2 denote clean and fouled evaporator tube ($R_D = 0.45 \text{ m}^2 \text{ }^\circ\text{K/KW}$) respectively for baggase black liquor. For comparison purposes the corresponding results for bamboo black liquor are reproduced in these figures and the curves marked C-1 and D-1 represent clean and dirty tubes ($R_D = 0.45 \text{ m}^2 \text{ }^\circ\text{K/KW}$) respectively. Baggase and Bamboo black liquors are very good examples for demonstrating the role of engineering properties of process liquors on the performance of evaporators.

The curve in Fig. 6.20 show that the temperature profile (C-1) and (D-1) for bamboo black liquor; and (C-2) and (D-2) for baggase black liquor are similar. The length of the nonboiling region is 2.13 meter and 2.75 meter for the clean and fouled tubes respectively handling baggase black liquor and the corresponding value for bamboo black liquor are 0.92 and 1.83 meter. This shows that the nonboiling section length is increased

Fig.6.20 Variation of liquor temperature along tube length.

Fig.6.21-Overall heat transfer coefficient along tube length.

Fig.6.22-Variation of liquor concentration along tube length.

by a factor of 2.3 and 1.5 for clean and fouled surfaces respectively when changing over from bamboo to baggase black liquor. This can be attributed to the lower value of the overall heat transfer co-efficients for baggase black liquor as a result of its higher viscosity.

The curves in Fig. 6.21 show that the value of overall heat transfer co-efficient for bamboo black liquor in the nonboiling section is 2.5 times the value for baggase black liquor. This effect of liquor viscosity on the overall heat transfer co-efficient decreases the evaporation rate as may be observed by the curves in Fig. 6.22 (Curves C-1, C-2 and D-1, D-2). The viscosity of the Bamboo and baggase black liquor for the concentration range of Fig. 6.22 are given below in Table 6.4.

Table 6.4: Viscosity Range for Bamboo & Baggase Black Liquors in a Clean Tube

	Bamboo Black Liquor		Baggase Black Liquor	
	Inlet	Exit	Inlet	Exit
1. Nonboiling section-				
Temperature, °C	50.0	106.0	50.0	102.4
Solid Concentration, %	12.0	12.0	12.0	12.0
Viscosity, cp	0.9	0.45	4.7	1.9
2. Boiling section-				
Temperature, °C	106.0	95.3	102.4	86.2
Solid Concentration, %	12.0	27.8	12.0	25.9
Viscosity, cp	0.45	1.1	1.9	9.8

The results of the above comparison clearly shows that a given evaporator can be effectively used using preheated baggase black liquor to reduce the length of the nonboiling section. The role of wide variation in physical properties of black liquor can be appreciated in evaluating the performance of commercial plants utilizing multiple effect evaporators including auxiliary heat recovery equipments such as liquid preheater, heat exchangers, condensate vaporizers, product vaporizers, vapor bleed etc. Evaporation plant in the chemical recovery system of kraft pulp mill usually consist of 4-7 effects with many of the heat recovery features listed above. The computational scheme for the single effect evaporation developed in this investigation can be applied to multiple effect evaporators which can be suitably modified to incorporate heat recovery features in the simulation programme.

CHAPTER 7

SUMMARY

Simulation programme developed in this work based on slip model for two phase flow can give reliable values of the heat transfer rates in the long tube vertical evaporators. The model has been applied to black liquors over the concentration range of 12-28% dissolved solids and the values of the overall heat transfer co-efficients obtained agree very well with the experimental values reported in literature. The profiles of liquor temperature, concentration, heat flux and overall heat transfer co-efficients along the evaporator tube length are obtained for bamboo, baggase and pine black liquors and the influence of solution viscosity on the lengths of nonboiling, nucleate boiling and annular film regions in a given evaporation unit is illustrated. Reduction in evaporator capacity resulting from the dirt resistance to heat transfer from scale deposits can be predicted by this programme. The model can also be used to predict changes in evaporation capacity and the necessary auxiliary heat exchange equipment when the process liquor exhibits a large change in the viscosity.

NOMENCLATURE

A_L	Cross section of liquid stream, Sq ft.
A_G	Cross section of vapor stream, Sq.ft.
C_1	Cross sectional area of tube, Sq ft
C_L	Specific heat of liquid, Btu/lb °F
C_p	Specific heat of vapor at constant pressure, Btu/lb °F
D	Tube diameter, ft
g	Gravitational Acceleration, ft/sec ²
g_c	Conversion factor, 32.2 lb-ft/lb _f . sec ²
G_G	Mass flux of vapor stream, lb/sq ft. sec.
G_L	Mass flux of liquid stream, lb/sq ft. sec.
G	Mass flux of liquid-vapor stream, lb/sq ft. sec
J	Mechanical equivalent of heat, 778.17 ft-lb _f /Btu
P	Pressure, lb _f /sq ft
$\frac{dP}{dZ}$	Total pressure drop per unit length, lb _f /cu ft.
$\frac{dP_f}{dZ}$	Frictional pressure drop per unit length, lb _f /cu ft.
Q	Heat flux, Btu/hr. sq ft.
S	Solid concentration, Wt %
T	Temperature, °F
T_o	Reference temperature, °F
U	Velocity of homogeneous phase
V_G	Velocity of vapor stream, ft /sec

V_L	Velocity of liquid stream, ft/sec.
W_G	Mass flow rate of vapor, lb/sec
W_L	Mass flow rate of liquid, lb/sec
W_T	Total mass flow rate, lb/sec
W_S	Work done by the system on surrounding, Btu/lb-m
X	Quality of vapor-liquor mixture = W_G/W_T
Z	Tube length, ft
ρ_L	Density of liquid, lbm/cu ft.
ρ_G	Density of vapor, lbm/ cu ft.
ρ	Density of vapor-liquid mixture, lbm/ cu ft.
τ_w	Shear stress at the wall, lb _f /sq ft.
α	Void fraction
λ	Heat of vaporization, Btu/lbm

APPENDIX ATWO PHASE FRICTIONAL PRESSURE DROP

Lockhart & Martinelli⁽²⁴⁾ have analyzed four types of two phase flow mechanisms which exist during the simultaneous flow of a liquid and a gas or vapor: (1) Turbulent-Turbulent flow (2) Viscous-turbulent flow (3) Turbulent-viscous flow (4) Viscous-Viscous flow (flow of both liquid and gas may be viscous). This analysis is based on the following assumptions:

1. Static pressure drop for the liquid phase must equal the static pressure drop for the gaseous phase regardless of the flow pattern, as long as an appreciable radial static pressure difference does not exist.
2. The volume occupied by the liquid plus the volume occupied by the gas at any instance must equal the total volume of the pipe.
3. Flow mechanism transition criteria:

$Re_{gp} \geq 2000$ the gas phase is turbulent

$Re_{lp} \leq 1000$ flow of liquid is viscous

$$\text{where } Re_{gp} = \frac{4 W_g}{\pi D_p \mu_g} ; Re_{lp} = \frac{4 W_l}{\pi D_p \mu_l}$$

Lockhart & Martinelli defined a parameter X (two phase flow modulus) for the different flow mechanisms given by Eq.A-1 to Eq.A-4.

$$X_{tt}^2 = \left(\frac{W_l}{W_g} \right)^{1.8} \left(\frac{\rho_g}{\rho_l} \right) \left(\frac{\mu_l}{\mu_g} \right)^{0.2} \quad (A-1)$$

$$X_{vt}^2 = \frac{C_1}{C_g} \text{Re}_{gp}^{-0.8} \frac{W_1}{W_g} \frac{\rho_g}{\rho_1} \frac{\mu_1}{\mu_g} \quad (\text{A-2})$$

$$X_{tv}^2 = \frac{C_1}{C_g} \text{Re}_{lp}^{0.8} \frac{W_1}{W_g} \frac{\rho_g}{\rho_1} \frac{\mu_1}{\mu_g} \quad (\text{A-3})$$

$$X_{vv}^2 = \frac{W_1}{W_g} \frac{\rho_g}{\rho_1} \frac{\mu_1}{\mu_g} \quad (\text{A-4})$$

The value of constants C_1 , C_g , n , m for use in equation A-1 to A-4 are given below:

Type of Flow	t-t	v-t	t-v	v-v
n	0.2	1.0	0.2	1.0
m	0.2	0.2	1.0	1.0
C_1	0.046	16.0	0.046	16.0
C_g	0.046	0.046	16.0	16.0

The following equations are obtained by least square techniques for the parameter $\phi_g \left[\left(\frac{\Delta P}{\Delta L} \right)_{TP} / \left(\frac{\Delta P}{\Delta L} \right)_g \right]$ and R_g (fraction of tube filled with the vapor) as a function of corresponding X , using curves given by Lockhart & Martinelli for ϕ_g and R_g .

$$\phi_{gtt} = \text{Exp} (1.54623 + 0.48518 \log X_{tt} + 0.044 (\log X_{tt})^2) \quad (\text{A-5})$$

$$\phi_{gvt} = \text{Exp} (1.36397 + 0.49115 \log X_{vt} + 0.05209 (\log X_{vt})^2) \quad (\text{A-6})$$

$$\begin{aligned} \phi_{gtv} = & \text{Exp} (1.35883 + 0.52153 \log X_{tv} + 0.05963 (\log X_{tv})^2 \\ & - 0.0013 (\log X_{tv})^3 - 0.0004 (\log X_{tv})^4) \end{aligned} \quad (\text{A-7})$$

$$\begin{aligned} \phi_{gvv} = & \text{Exp} (1.0705 + 0.5520 \log X_{vv} + 0.0881 (\log X_{vv})^2 \\ & - 0.0026 (\log X_{vv})^3 - 0.0012 (\log X_{vv})^4) \end{aligned} \quad (\text{A-8})$$

$$R_g = \text{Exp} (-0.2235 - 0.10046 \log X - 0.0404 (\log X)^2 - 0.0066 (\log X)^3) \quad (\text{A-9})$$

$$\phi \left[\left(\frac{\Delta P}{\Delta L} \right)_{TP} / \left(\frac{\Delta P}{\Delta L} \right)_L \right] \text{ and } R_1 \text{ (fraction of tube filled with}$$

the liquor) can be given by Eq. A-10 and A-11.

$$\phi_1 = \phi_g / X \quad (\text{A-10})$$

$$R_1 = 1 - R_g \quad (\text{A-11})$$

Parameter α (flow type modulus for liquid) and β (flow type modulus for vapor) are given by equation A-12 and A-13.

$$\alpha = R_1^4 \phi_{ltt}^{3.33} = R_1^2 \phi_{lvt}^2 = R_1^4 \phi_{ltv}^{3.33} = R_1^2 \phi_{lvv}^2 \quad (\text{A-12})$$

$$\beta = R_g^4 \phi_{gtt}^{3.33} = R_g^4 \phi_{gvt}^{3.33} = R_g^2 \phi_{gtv}^2 = R_g^2 \phi_{gvv}^2 \quad (\text{A-13})$$

D_1 (hydraulic diameter of liquid flow) and D_g (hydraulic diameter of gas flow) can be given by Eq. A-14 and A-15.

$$\left(\frac{D_p}{D_1} \right)^2 = \frac{\alpha}{R_1} \quad (\text{A-14})$$

$$\left(\frac{D_p}{D_g} \right)^2 = \frac{\beta}{R_g} \quad (\text{A-15})$$

Total frictional pressure drop can be calculated by Eq. A-16 by using equations A-1 to A-15.

$$\left(\frac{\Delta P}{\Delta L} \right)_{\text{fric}} = \frac{2 \left(\frac{4}{\pi} \right)^{2-n} C_1 \mu_1^n W_1^{(2-n)}}{D_p^{(5-n)} \rho_1 g} \alpha^{(n-2)} \left(\frac{D_p}{D_1} \right)^{(5-n)} \quad (\text{A-16})$$

For the case when $R_{\text{egp}} > 2100$ and $R_{\text{elp}} > 8000$, there is a correction by Davis⁽²⁵⁾. For this range Davis defined the parameter X given by Eq. A-17.

$$X = 0.19 \left(\frac{W_1}{W_g} \right)^{0.9} \left(\frac{\rho_g}{\rho_1} \right)^{0.5} \left(\frac{\mu_1}{\mu_g} \right)^{0.1} \left(\frac{V_m^2}{D_p g} \right)^{0.185} \quad (\text{A-17})$$

$$\text{Where } V_m = \left(\frac{W_1}{\rho_1} + \frac{W_g}{\rho_g} \right) / \frac{\pi D_p^2}{4}$$

Notations:

$(\Delta P / \Delta L)_{\text{fric}}$ = pressure drop per unit length due to friction, lb-f/cu ft

W_1, W_g = liquid flow rate and gas flow rate respectively, lb/sec.

D_p = Dia of pipe, ft. μ = viscosity, lb-m/sec.ft

ρ = Density lb-m/cu ft.

APPENDIX B

COMPARISON OF TWO METHODS TO CALCULATE NONBOILING SECTION HEAT TRANSFER

CO-EFFICIENT

For nonboiling section heat transfer co-efficient, two correlations can be used: equation given by Badger et.al.⁽⁶⁾ and equation of Martinelli & Boelter⁽⁴⁷⁾. Badger's correlation gives overall whereas Martinelli & Boelter's expression would give convective heat transfer co-efficient for inside liquid and includes the effect of natural convection. Badger's correlation-

$$U_{NB} = 0.06 \left(\frac{C \Delta T_{NB} f^2}{\mu_{NB}} \right)^{0.7} \quad (B-1)$$

Martinelli & Boelter's correlation-

$$Nu_{a.m.} = 1.75 F1 \left[\frac{GZ_{a.m.} + 0.0722 F2 \left(\frac{Gr Pr}{X/dw} \right)^{0.84}}{w} \right] \quad (B-2)$$

$$\text{where } F1 = \frac{3.14 Nu_{a.m.} / GZ_{a.m.}}{\log (2 + 3.14 Nu_{a.m.} / GZ_{a.m.}) (2 - 3.14 Nu_{a.m.} / GZ_{a.m.})} \quad (B-3)$$

$$F2 = 1 - .408 \sqrt{Nu_{a.m.} / GZ_{a.m.}} \quad \frac{Nu_{a.m.}}{GZ_{a.m.}} < 1.85 \quad (B-4)$$

$$= -1.63 \left(\sqrt{Nu_{a.m.} / GZ_{a.m.}} - 2 \right) \quad 1.85 < \frac{Nu_{a.m.}}{GZ_{a.m.}} < 2.0 \quad (B-5)$$

X = nonboiling section length, ft

Over all heat transfer co-efficient and nonboiling section length are calculated for process conditions of Badger data 7 (see Table 6.1) by

using eq. B-1 and eq. B-2; and are compared below:

Table B-1: Comparison of Results by Badger & Martinelli's Correlations

	Overall Heat Transfer Co-efficient Btu/hr sq ft °F	Nonboiling section length, ft
Badger et.al ⁽⁶⁾	90	6.32
Martinelli & Boelter ⁽⁴⁷⁾	84	6.53

As clear from Table B-1, both equations lead to nearly same results and for computational purposes it is simpler to use Badger correlation than Martinelli and Boelter expression; in the latter expression nonboiling section length is an implicit variable which will require a trial & error procedure for solution.

APPENDIX CTable C.1 - Antoine Equation Constants for Water

Temp Range °C	Antoine Equation Constant

760 -1500	7.9186968	1636.909	224.92

$$T = \frac{B}{A - \log_{10} P} - C$$

T = temperature, °C

P = pressure, mm of Hg

APPENDIX DCOMPUTER PROGRAMME LISTING

C1	Cross sectional area of the tube
TS	Steam temperature
DP	Internal dia. of tube
XL	Length of the tube
DZ	Differential length increment for computation
WL	Liquor mass flow rate
TI	Inlet temperature of the feed
S	Solid content in the feed
P	Pressure in the tube
WG	Vapor mass flow rate
BPT	Boiling point elevation
GPRLF	Frictional pressure gradient
UN	Overall heat transfer co-efficient
Q	Heat flux
DT	Temperature difference for the differential section
DPT	Pressure drop in the differential section
QT1	Heat transfered in the differential section
QT	Total heat transfered
X	Vapor quality
V	Homogeneous phase velocity
DEG	Density of vapor

XMUG	Viscosity of vapor
HV	Latent heat of vaporization for water
CP	Specific heat of vapor
DX	Vapor quality difference for the section
DS	Solid content change in the differential section
RGI	Void fraction at the inlet of the section
RGO	Void fraction at the outlet of the section
DV	Homogeneous phase velocity difference in the section
HTB	Heat transfered in the boiling section
US2	Average boiling heat transfer co-efficient
DEL	Density of liquor
CL	Specific heat of liquor
UN	Nonboiling section overall heat transfer co-efficient
XMUL	Viscosity of liquor
WT	Feed liquor mass flow rate
REG	Reynold no for vapor
REL	Reynold no for liquor
RL	Liquid volume fraction in the tube
KL	Thermal conductivity of liquor
ST	Surface tension of liquor
H	Inside tube heat transfer co-efficient for liquor
HS	(Wall + Steam side) Heat transfer co-efficient
U	Overall heat transfer co-efficient in the boiling section

DM	Mean diameter of the tube
DPO	Outside diameter of the tube
SK	Thermal conductivity of tube material
HO	Steam side heat transfer co-efficient
A,B,C	Antoine equation constants
